it looks the first PC (which I said it was), but that this isn't the corrected one (for CO2 growth

effects). Can you check whether it is the right one? Malcolm says that Idso (who was on

E&E) will say that the increase in that series is not climatic but due to fertilization. This

would not look good obviously. Idso was on a paper with Don Graybill re fertilisation effects

on bristlecones.

If you need to send a revised series for this top series in Fig 2 then send it to Tim.

Tim has done this plot so can make the alterations if another series is needed. If you think

that the series is OK then we'll leave it. If you do change it will affect Fig 2 of the GRL also

but probably not to any noticeable effect - at least at the size the plot will be.

Tim will send round the copyright forms to all and reprint forms. Tell Tim if you want any.

Seems like the pdf will do.

Cheers

Phil

PS Tell Lorraine I'm not always emailing you - but Malcolm thought the above was important.

I assumed you would have sent the corrected one you used in GRL in 1999.

Hi Ellen,

I'm still travelling, and have only intermittent email access. I'm pretty sure Phil is travelling now too, so I'm hoping Keith or Tim can help out here.

I think we actually discussed two small changes from the final version Phil sent you. This involved adding Malcolm Hughes as a co-author (his name was accidentally left off the list), and changing the wording of one sentence slightly. I believe that Tim and Keith have these changes, and hopefully they can submit this via GEMS? If not, will have to wait until Phil or I have a solid internet connection to do this (that will likely be at IUGG in Sapporo in about 2 weeks).

Thanks for bringing this to our attention. Phil--if you're reading email, any way you can help out here?

thanks all,

mike

At 04:36 PM 6/23/2003 -0400, Ellen Mosley-Thompson wrote:

Phil,

I just learned from AGU that you did not submit the revised version back to AGU via the GEMS system. Can you or Mike do this as soon as possible? I would like to get this paper moving through AGU. Fred Spilhaus still has to approve it - he approves all Forum pieces - so this adds a layer that will cost us time.

Thanks

Ellen

P.S. I have copied everyone who might be able to handle this in your and Mike's absence. Thanks

At 05:13 PM 06/20/2003 +0100, you wrote:

Dear Ellen,

I'm off on Sunday, but I've managed to get the revisions done. The revised pdf is attached. This contains a reduced size manuscript by about 10 lines and we've reduced the

references to the absolute minimum. This is still 30. If we go any lower we have to change the

figures. As we are commenting on a paper we need to specifically reference all the series we use.

Thanks for going through so quickly.

If further changes are required I won't be here so can you email either Keith Briffa

or Tim Osborn (k.briffa@uea.ac.uk, t.osborn@uea.ac.uk) .

I will ask Keith and Tim to get the copyright forms rolling.

Cheers

Phil

At 13:50 18/06/03 -0400, eos@agu.org wrote:

Dear Dr. Mann: (copy to Phil Jones)

I am pleased to accept "On Past Temperatures and Anomalous late-20th Century Warmth" for publication in Eos with the provision that in your final submission you modify to the first paragraph slightly so that it is fully consistent with the text of the AGU statement on climate change and greenhouse gases:

[1]http://www.agu.org/sci_soc/policy/climate_change_position.html

Note that first sentence of your paper indicates that the AGU statement includes the inference that there is a high probability I cannot find the words high probability in the AGU statement (unlike IPCC that does state "high probability."). It is critical that the introductory paragraph is carefully constructed so as not to diminish any of the points you make in the Forum piece. I suggest a modification of your first paragraph - please feel free to further modify this.

Evidence from Gases," that there is a compelling basis for concern over future climate changes, including increases in global mean surface temperatures, due to increased concentrations of greenhouse gases, primarily from fossil fuel burning. If this is too long, you might wish to break it into two sentences. This says the same thing as your original intro sentence but is fully consistent with the text of the AGU statement.

Also in the first paragraph would you agree to this change?

... such anomalous warm cannot be fully explained natural factors (Added the word "fully" to indicate that some but not all of the anomalous warming can be explained by natural factors.)

Another suggestion is to remove the second reference to the AGU policy (second paragraph). What about ... these claims in light of the fact that they have

The content of the Forum piece is just fine, but I did find a few minor problems that you need to fix in the final submission.

1) 3rd paragraph line 8 - reference to Jones et al. (1998) - this date occurs in several places in the paper and should be Jones et al. 1999; e.g., point (2) line 3

2) page 2 - the second (2) point

last 3 lines: remove double period after U.S.; also that sentence reads awkwardly - try a comma after the word 'cancelling'.

3) the second paragraph of point 2 (2); last three lines: this is awkward; the word "apparent" is out of place; I think this should this read apparent coldness and warmth differ

4) point 3) last line of first paragraph - change ... insight to (Remove in from

into)

5) references - the Jones et al. 1999 reference is formatted differently than the rest (put date at end).

Finally - everywhere throughout the text et al should be corrected to et al (The period is consistently absent)

Before publication, your article will be edited to reflect the Eos newspaper style, including a possible change in the headline. We will send the edited version to you for review and final approval before the article is published.

Please note that before we can proceed with production work on your submission, a copyright transfer agreement and reprint order form must be completed and returned to AGU. These forms may be printed* from the AGU web site:

[2]http://www.agu.org/pubs/journal_forms/EosCopyright.pdf

[3]http://www.agu.org/pubs/journal_forms/EosReprint_orders.pdf.

For information on the production process, please contact Shermonta Grant, Eos Production Coordinator, at +202.777.7533 or sgrant@agu.org.

In the absence of information from you to the contrary, I am assuming that all authors listed on the manuscript concur with publication in its final accepted form and that neither this manuscript nor any of its essential components have been published previously or submitted to another journal. The AGU Guidelines for Publication emphasize that: "It is unethical for an author to publish manuscripts describing essentially the same research in more than one journal of primary publication."

Thank you for your contribution to Eos.

Sincerely,

Ellen Mosley-Thompson

Tim,

I suggest we let Eos size the figures, etc. Then, in the end, we can simply substitute a version of Figure 2 w/ the correlations added at the proof stage. Anything else will slow down the publication of the manuscript unnecessarily, in my opinion.

Phil and I have already discussed--we agree that the low weight given to the record in the Mann and Jones composite treats the record appropriately...

mike

At 02:37 PM 6/24/2003 +0100, Tim Osborn wrote:

Hi Tom,

In Phil's absence I was just now looked at his PC because I needed some files/emails for a separate matter, and I noticed that you had emailed Phil/Ray/Mike concurring with Ray's concerns. Until I saw that, I hadn't realised that anyone else had commented on Yang et al.

Keith and I discussed exactly this issue this morning, and though Keith also had concerns about the record (I haven't read their paper, so can't comment) we decided to leave things as they were because: (i) Mike suggested adding correlations to the figure at the proof stage rather than now; (ii) I wasn't sure how to word a caveat about Yang et al. without making it seem odd that we were including a doubtful record and odd that we hadn't added caveats about some of the other records.

The current status is that the version I circulated has been submitted back to EOS (because of the reasons given above), and Ellen Mosley-Thompson has approved it. It needs to be reviewed internally at AGU by either Fred Spilhaus or an Associate Editor. It will then be edited to reflect the Eos newspaper style.

I've cc'd this to Mike and Phil to see what they want to do. I/we can put a hold on the processing of the current submission and then submit a new version with revised figure and caption. Alternatively we could wait and see what it's like after EOS have edited it, and then make any final modifications at that stage.

Over to you/Mike/Phil.

Cheers

Tim

Thanks Keith,

I just read your email after reading the others. We actually eliminate records with negative correlations (this is mentioned briefly in the GRL article,), and we investigated a variety of weighting schemes to assure the basic robustness of the composite--but I certainly endorse your broader point here. Many of these records have some significant uncertainties or possible sources of bias, and this isn't the place to get into that. The uncertainties get at this, at some level, and other places (e.g. the Reviews of Geophysics paper Phil and I are drafting) will provide an opportunity to discuss these kinds of issues in more detail--we will certainly be seeking advice (either officially or unofficially) from each of you once we have finalized the draft of that...

Now back to my honeymoon...

mike

At 02:38 PM 6/24/2003 +0100, Keith Briffa wrote:

To keep you informed , here is a reply to Tom Wigley re his request to "deal with Ray's Comments" re the China series in EOS piece

Tom

Tim has just told me of your message expressing concern about the China series , and your statement of the necessity to "deal with Ray's comment" and add in the "small adjustment to the Figure Caption" . .

We (I and Tim) decided to get this off as soon as possible to Ellen (AGU) , as we had been asked to do (and as requested by Ellen). Hence it went off earlier today (and before your message arrived). Mike was aware of Ray's comment and was happy to leave any amendment to the text "until the proof stage" .

In my opinion it is not practical (or desirable) to try to "qualify " any one record in this limited format. It was a majority decision to leave the Mann and Jones 2000-year series in the Figure 1 (as it was to remove the Briffa and Osborn tree-ring based one) , and the details of the logic used to derive the Mann and Jones series is to be found in the (cited) text of their paper. Signing on to this letter , in my mind. implies agreement with the text and not individual endorsement of all curves by each author. I too have expressed my concern to Phil (and Ray) over the logic that you leave all series you want in but just weight them according to some (sometimes low) correlation (in this case based on decadal values). I also believe some of the series that make up the Chinese record are dubious or obscure , but the same is true of other records Mann and Jones have used (e.g. how do you handle a series in New Zealand that has a -0.25 correlation?) . Further serious problems are still (see my and Tim's Science comment on the Mann 1999 paper) lurking with the correction applied to the Western US tree-ring PC amplitude series used (and shown in Figure 2). There are problems (and limitations) with ALL series used. At this stage , singling out individual records for added (and unavoidably cursory added description) is not practical. We were told to cut the text and References significantly - and further cuts are implied by Ellen's messages to us. If you wish to open this up to general discussion , it may be best to wait 'til the proof stage and then we can all consider the balance of emphasis - but we had also better guard against too "selective" a choice of data to present? If you want to get a

somewhat wider discussion of this point going in the meantime , feel free to forward this to whoever you wish along with your disagreement , while we wait on the response from AGU.

Best wishes

Keith

Subject: Dear Prof. Hulme

Dear Prof. Hulme,

Thank you for your letter proposing that the Tyndall Centre and TERI jointly produce a series of yearbooks on climate change. May I congratulate you on this excellent idea! I am convinced that a market exists for precisely such a publication, and am delighted that you thought of TERI as a partner in this venture.

I am putting down some initial thoughts on the proposed publication and the suggested contents that you had sent.

While there is a lot of information and related data available on climate change, it is scattered. On the one hand we have the IPCC assessment on the state of knowledge about climate change, and on the other the WMO's annual bulletins. Similarly, the UNFCCC compiles GHG inventory information from periodically submitted National Communications, while the IEA presents annual fuel combustion emission statistics. In such a scenario, the metier

of our Yearbook would be to synthesise the current knowledge on climate change. As mentioned in your note, it would present this information in a clear and visually appealing manner. Moreover, it would go into climate change issues in more detail than say, the annual World Resources brought out by WRI.

The Foreword - and perhaps an Emerging Issues section at the end of the book - could comment on scientific and political issues, which are otherwise not discussed in either the IPCC Reports or in the types of publications mentioned above.

In the draft table of contents, there are two sections that are slightly different in character from the others. In the chapter on national policies, we may choose between alternative structures:

1 By Annex I country

2 By type of policy/instrument (e.g. CDM, international trading regimes, taxation, etc)

The proposed chapter on Social Change and Adaptation is important to complete the set of topics/issues covered in the Yearbook, but is probably the most complex in terms of scope/structure. One option that we could discuss is to cover adaptation policies not in chapter 7, but in chapter 9, and to highlight studies of community and local government level implementation.

With such a scope, the media would also be an important part of the audience for this yearbook

I do appreciate that producing this Yearbook would involve significant commitment in terms of time and effort if all relevant literature is to be reviewed. However, by teaming up authors from our two organisations, I am confident that we will provide an impartial yet balanced North-South perspective to the Yearbook. For specialised subjects, like the chapter on business, we may even think of invited chapters, by say the WBCSD.

You may also be interested to know that TERI also brings out a yearbook focusing on India, called the TERI Energy Directory, Database, and Yearbook (TEDDY). This publication has a readership of 15000-20000, reaching out to government, corporates, individual researchers, and libraries in India and overseas.

These are just some initial thoughts, and my colleagues can be in touch with your team to develop this outline further. Ms Ulka Kelkar (ulkak@teri.res.in) will coordinate this effort on behalf of TERI.

We look forward to working with you on this Yearbook.

With kind regards,

Yours sincerely,

R.K. Pachauri

Ciao Mick

Just back from Tuscany and still ploughing through accumulated emails. Where the UEA invoice is concerned, I just opened an invoice from UEA for SEK 71,074.09 and would be most obliged if you could let me know if this is the correct amount, so I can get it paid?

Please give my regards to Sarah and let her know that Tuscany is still as beautiful as ever, but a bit more expensive than before but still cheaper than the UK. We also went to spend a few days in Umbria where some friends of ours had rented a lovely villa with magnificent views, gardens, pool, etc.

Best regards
Jenny

Hi Mick,

Sara has suggested that with the timetable given, that we ought to plan on the extension until end February 2004. I have then started to change the budget to add some more time. As we have already used the funds for one (June) issue of the three planned, I thought we would just add some days as follows:

Mick 5
Sarah 10
Mike Salmon 2.5
Gerry 4
Johan 4
Jenny 2

This would increase the total funds to 1,315,813 from 1,178,000, an increase of 137813 SEK (about £10,000). The publication cost for March 2003 would be in the new proposal, but all the work will have been done in Jan/Feb.

Does that sound OK?

Trevor

A quick update:

1. I'm arranging a meeting between our team and the Museums Service (including I hope the director) late July to discuss next stage. I'll consult Chris Flack about possible dates. They are ready to push ahead with the next stage.

2. N County Council now appear well and truly behind the project and want to bring development responsibility into their Economic Development Unit. Good news in terms of political will, but some concern about loss of control and transformation into a tourism project.

Think we need to resolve how best this initiative might relate to the linking CRED initiative, as discussed, and reach understanding with Museums Service sooner rather than later? Unless it's premature?

Finally, Melissa Burgan, ex MSc student, now with NCC transport division is very impressed with way CRED has been taken seriously by county council politicians. I assume her assessment is accurate!

<x-flowed>

Dear Keith, thanks for the update. I think I am reading much the same message as you do. I also agree that we need focus, and not too many groups involved. In terms of where the focus should be I agree that DOCC is too wide, and my feeling now is to dissolve it and reorganise under another heading with fewer groups, perhaps as an IP if Brussels allows. I do not have any preconceived notions as to where the co-ordinations should lie.

I agree with you that integration with biogeochemistry is not straight forward with Holocene climate variability except for the vegetation feedback which may be important.

I also know of one other palaeo-based initiative, ICON, dealing with the thermohaline circulation, coordinated by Rainer Zahn. We are involved. This will be submitted for the call just launched under the hot spots in the climate system heading, but may be brought over to the next call if unsuccessful (probably). We are involved there with a number of modelling centres and many of the palaeoceanography labs.

I guess we should discuss a bit further after summer has passed what to do. I am very keen on the science of Holclim and hope to be able to develop this initiative with you and others.

Last thing - any idea of when the conference Brussels wants is going to happen?.

I am away for two weeks on the Greek islands, but then I am back again.

Cheers,
Eystein

Dear Rick, Keith and Eystein,

It is certainly good news that FP6 will have a climate change and paleo related call. My personal feeling is that whatever paleo proposal(s) eventually do go in that it would be a good thing to specifically include the PAGES office in Bern as a participant in the network. This would, I believe, help the network by providing an international context and the many PAGES resources for outreach within Europe, and inclusion of non-europeans. On the other side of the coin, PAGES is currently seeking to broaden our support base beyond USA and Switzerland and participation in an EU framework proposal would be an ideal way to do this, given the strong representation of European scientists within the PAGES community. If, however, you have reason to believe that explicit inclusion of the PAGES office in the list of partner organizations would reduce the chance of success of such a proposal, then of course don't do it. Basically, I would much appreciate being kept in the loop with your plans and am happy to participate, and offer the help of PAGES, in any way I that you deem useful.

Cc: Tom Wigley <wigley@ucar.edu>, "Michael E. Mann" <mann@virginia.edu>, Mike Hulme <m.hulme@uea.ac.uk>

Dear Phil,

In June 2003, Climate Research published a paper by David Douglass et al. The "et al." includes John Christy and Pat Michaels. Douglass et al. attempt to debunk the paper that Tom and I published in JGR in 2001 ("Accounting for the effects of volcanoes and ENSO in comparisons of modeled and observed temperature trends"; JGR 106, 28033-28059). The Douglass et al. paper claims (and purports to show) that collinearity between ENSO, volcanic, and solar predictor variables is not a serious problem in studies attempting to estimate the effects of these factors on MSU tropospheric temperatures. Their work has serious scientific flaws - it confuses forcing and response, and ignores strong temporal autocorrelation in the individual predictor variables, incorrectly assuming independence of individual monthly means in the MSU 2LT data. In the Douglass et al. view of the world, uncertainties in predictor variables, observations, etc. are non-existent. The error bars on their estimated ENSO, volcano, and solar regression coefficients are miniscule.

Over a year ago, Tom and I reviewed (for JGR) a paper by Douglass et al. that was virtually identical to the version that has now appeared in Climate Research. We rejected it. Prior to this, both Tom and I had engaged in a long and frustrating dialogue with Douglass, in which we attempted to explain to him that there are large uncertainties in the deconvolution of ENSO, volcano, and solar signals in short MSU records. Douglass chose to ignore all of the comments we made in this exchange, as he later ignored all of the comments we made in our reviews of his rejected JGR paper.

Although the Douglass et al. Climate Research paper is largely a criticism of our previously-published JGR paper, neither Tom nor I were asked to review the paper for Climate Research. Nor were any other coauthors of the Santer et al. JGR paper asked to review the Douglass et al. manuscript. I'm assuming that Douglass specifically requested that neither Tom nor I should be allowed to act as reviewers of his Climate Research paper. It would be interesting to see his cover letter to the journal.

In the editorial that you forwarded, Dr. Kinne writes the following:

"If someone wishes to criticise a published paper s/he must present facts and arguments and give criticised parties a chance to defend their position." The irony here is that in our own experience, the "criticised parties" (i.e., Tom and I) were NOT allowed to defend their positions.

Based on Kinne's editorial, I see little hope for more enlightened editorial

decision making at Climate Research. Tom, Richard Smith and I will eventually publish a rebuttal to the Douglass et al. paper. We'll publish this rebuttal in JGR - not in Climate Research.

With best regards,

Ben

Hi Tom,

I'm not sure what format to try if ASCII doesn't work for you. I've attached the same ones again, in case it was just some random reason that corrupted the files. If this doesn't work, then please suggest a format I should try.

The name I have is Yamal not Yarnal. Yamal is coastwards (northward) of the "Polar Urals" and is at a lower elevation than the Polar Urals record. The latitude/longitude I have for it is:

67.5 N, 70 E

Hope that helps

Tim

At 21:40 07/07/2003, you wrote:

Hi Tim, thanks for sending the data - unfortunately I cannot open it, can you send it in some other format? tom

ps what is the location of the Yarnal site?

Hi Tom

Sorry for not replying sooner - its been a hectic week (or two)!

The new Mann and Jones 2000-year series I don't actually have. It appears in Figure 1 of our EOS piece, of course, but Scott Rutherford generated that figure. I generated Figure 2 for EOS and that has the Yamal, Tornetrask, western US and western Greenland O18 stack in it. So I have these data and they are attached in the following files.

western US and western Greenland are in file "mann12prox.dat". I didn't have time to extract just these two series from the full file, so the file contains 11 others series too. Please do **not** use the others because I'm not sure whether I am free to distribute them or not - I just haven't time to extract the 2 you want. I'm sure I can trust you not to use anything that I shouldn't have sent! The top of the file lists the 13 series and the start/end years. These are in the same order as the 13 columns of data that then follow (the first column is simply year AD). So you should be able to find "westgrpfisher.dat" and "wustrees.dat".

The other files are "tornad.rcs" and "yamal.rcs" which are RCS-standardised tree-ring width series. I would really strongly suggest that you contact Keith Briffa about exactly what these series are and what the primary reference to them should be. The reason is that there are multiple version of Tornetrask and Yamal series and the differences are certainly not insignificant!

I'm not sure what the "units" of any of these series are, so I would suggest you normalise them in some way or do your own calibration.

Hope that helps

Cheers

Tim

Tom,

I'm off tomorrow to NCDC and then onto IUGG, so away 3 weeks in all. I've asked Tim, who's cc'd on this reply to send you what he can.

You also said sometime ago, you would send your new long series and your latest NH average. Can you do this sometime? Mike and I are making progress on RoG. When we get back we will be working on the figures. I realise you may want to add something once

Tim sends you the series, so if I (and Mike) can get something by July 10 that would be great.

We will be sending whole or part drafts of the RoG piece around - we have most of the text,

but we need the figures for people to look at as well. So you might get a draft in September.

Have a good few weeks.

Cheers

Phil

At 12:33 19/06/03 -0400, you wrote:

Phil,

would it be possible to obtain the Yamal, Tornetrask, and w. U.S. series you illustrate in the eos article? I too am putting together a slightly different long composite and would like to include these records.

would it also be possible to obtain the 2000 year northern hemisphere series? is that 30-90N summer? whatever, we have extended our forcing time series back to before 1 AD and would like to compare with some longer data.

thanks and regards, Tom

Dear All,

Keith and I have discussed the email below. I don't want to start a discussion of it and I

don't want you sending it around to anyone else, but it serves as a warning as to where the debate might go should the EOS piece come out.

I think it might help Tom (W) if you are still going to write a direct response to CR. Some of

de Freitas' views are interesting/novel/off the wall to say the least. I am glad that he doesn't

consider himself a paleoclimatologist - the statement about the LIA having the lowest temperatures since the LGM. The paleo people he's talked to didn't seem to mention the YD,

8.2K or the 4.2/3K events - only the Holocene Optimum. There are also some snipes at CRU and our funding, but we're ignoring these here. Also Mike comes in for some stick, so stay

cool Mike - you're a married man now !

So let's keep this amongst ourselves .

I have learned one thing. This is that the reviewer who said they were too busy was Ray.

I have been saying this to loads of papers recently (something Tom(w) can vouch for). It is

clear from the differences between CR and the ERE piece that the other 4 reviewers did not say much, so a negative review was likely to be partly ignored, and the article would still

have come out. I say this as this might come out if things get nasty.

De Freitas will not say to Hans von Storch or to Clare Goodess who the 4 reviewers were. I

believe his paleoclimatologist is likely to be Anthony Fowler, who does dendro at Auckland.

Cheers

Phil

Otto (and copied to Mike Hulme)

I have spent a considerable amount of my time on this matter and had my integrity attacked in the process. I want to emphasize that the people leading this attack are hardly impartial observers. Mike himself refers to "politics" and political incitement involved. Both Hulme and Goodess are from the Climate Research Unit of UEA that is not particularly well known for impartial views on the climate change debate. The CRU has a large stake in climate change research funding as I understand it pays the salaries of most of its staff. I understand too the journalist David Appell was leaked information to fuel a public attack. I do not know the source

Mike Hulme refers to the number of papers I have processed for CR that "have been authored by scientists who are well known for their opposition to the notion that humans are significantly altering global climate." How many can he say he has processed? I suspect the answer is nil. Does this mean he is biased towards scientists "who are well known for their support for the notion that humans are significantly altering global climate?"

Mike Hulme quite clearly has an axe or two to grind, and, it seems, a political agenda. But attacks on me of this sort challenge my professional integrity, not only as a CR editor, but also as an academic and scientist. Mike Hulme should know that I have never accepted any research money for climate change research, none from any "side" or lobby or interest group or government or industry. So I have no pipers to pay.

This matter has gone too far. The critics show a lack of moral imagination. And the Cramer affair is dragged up over and over again. People quickly forget that Cramer (like Hulme and Goodess now) was attacking Larry Kalkstein and me for approving manuscripts, in Hulme's words, "authored by scientists who are well known for their opposition to the notion that humans are significantly altering global climate."

I would like to remind those who continually drag up the Cramer

affair that Cramer himself was not unequivocal in his condemnation of Balling et al's manuscript (the one Cramer refereed and now says I should have not had published - and what started all this off). In fact, he did not even recommend that it be rejected. He stated in his review: "My review of the manuscript is mainly with the conclusions of the work. For technical assessment, I do not myself have sufficient experience with time series analysis of the kind presented by the authors." He goes on to recommend: "revise and resubmit for additional review". This is exactly what I did; but I did not send it back to him after resubmission for the very reason that he himself confessed to ignorance about the analytical method used.

Am I to trundle all this out over and over again because of criticism from a lobbyist scientists who are, paraphrasing Hulme, "well known for their support for the notion that humans are significantly altering global climate".

The criticisms of Soon and Baliunas (2003) CR article raised by Mike Hume in his 16 June 2003 email to you was not raised by the any of the four referees I used (but is curiously similar to points raised by David Appell!). Keep in mind that referees used were selected in consultation with a paleoclimatologist. Five referees were selected based on the guidance I received. All are reputable paleoclimatologists, respected for their expertise in reconstruction of past climates. None (none at all) were from what Hans and Clare have referred to as "the other side" or what Hulme refers to as people well known for their opposition to the notion that humans are significantly altering global climate." One of the five referees turned down the request to review explaining he was busy and would not have the time. The remaining four referees sent their detailed comments to me. None suggested the manuscript should be rejected. S&B were asked to respond to referees comments and make extensive alterations accordingly. This was done.

I am no paleoclimatologist, far from it, but have collected opinions from other paleoclimatologists on the S&B paper. I summarise them here. What I take from the S&B paper is an attempt to assess climate data lost from sight in the Mann proxies. For example, the raising on lowering of glacier equilibrium lines was the origin of the Little Ice Age as a concept and still seems to be a highly important proxy, even if a little difficult to precisely quantify.

Using a much larger number of "proxy" indicators than Mann did, S&B inquired whether there was a globally detectable 50-year period of unusual cold in the LIA and a similarly warm era in the MWP. Further, they asked if these indicators, in general, would indicate that any similar period in the 20th century was warmer than any other era.

S&B did not purport to do independent interpretation of climate time series, either through 50-year filters or otherwise. They merely adopt the conclusions of the cited authors and make a scorecard. It seems pretty evident to me that temperatures in the LIA were the lowest since the LGM. There are lots of peer-reviewed paleo-articles which assert the existence of LIA.

Frankly, I have difficulty understanding this particular quibble. Some sort of averaging is necessary to establish the 'slower' trends, and that sort of averaging is used by every single study - they average to bring out the item of their interest. A million year average would do little to enlighten, as would detailed daily readings. The period must be chosen to eliminate as much of the 'noise' as possible without degrading the longer-term signals significantly.

As I read the S&B paper, it was a relatively arbitrary choice - and why shouldn't it be? It was only chosen to suppress spurious signals and expose the slower drift that is inherent in nature. Anyone that has seen curves of the last 2 million years must recognize that an averaging of some sort has taken place. It is not often, however, that the quibble is about the choice of numbers of years, or the exact methodology - those are chosen simply to expose 'supposedly' useful data which is otherwise hidden from view.

Let me ask Mike this question. Can he give an example of any dataset where the S&B characterization of the source author is incorrect? (I am not vouching for them, merely asking.)

S&B say that they rely on the original characterizations, not that they are making their own; I don't see a problem a priori on relying on characterizations of others or, in the present circumstances, of presenting a literature review. While S&B is a literature review, so is this section of IPCC TAR, except that the S&B review is more thorough.

The Mann et al multi-proxy reconstruction of past temperatures has many problems and these have been well documented by S&B and others. My reading of the IPCC TAR leads me to the conclusion that Mann et al has been used as the basis for a number of assertions: 1. Over the past millennium (at least for the NH) the temperature has not varied significantly (except for the European/North Atlantic sector) and hence the climate system has little internal variability. This statement is supported by an analysis of model behaviour, which also shows little internal variability in climate models. 2. Recent global warming, as inferred from instrument records, is large and unusual in the context of the Mann et al temperature reconstruction from multi-proxies. 3. Because of the previous limited variability and the

recent warming that cannot be explained by known natural forcing (volcanic activity and solar insolation changes) human activity is the likely cause of the recent global change.

In this context, IPCC mounts a powerful case. But the case rests on two main foundations; the past climate has shown little variability and the climate models reflect the internal variability of the climate system. If either or both are shown to be weak or fallacious then the IPCC case is weakened or fails.

S&B have examined the premise that the globally integrated temperature has hardly varied over the past millennium prior to the instrumental record. I agree it is not rocket science that they have performed. They have looked at the evidence provided by researchers to see if the trend of the temperature record of the European/North Atlantic sector (which is not disputed by IPCC) is reflected in individual records from other parts of the globe (Their three questions). How objective is their assessment? From a purely statistical viewpoint the work can be criticised. But if you took a purely statistical approach you probably would not have sufficient data to reach an unambiguous conclusion, or you could try statistical fiddles to combine the data and end up with erroneous results under the guise of statistical significance. S&B have looked at the data and reached the conclusion that probably the temperature record from other parts of the globe follows the same pattern as that of the European/North Atlantic sector. Of the individual proxy records that I have seen I would agree that this is the case. I certainly have not found significant regions of the NH that were cold during the medieval period and warm during the Little Ice Age period that are necessary offsets of the European/North Atlantic sector necessary to reach a hemispherically flat pattern as derived by Mann et al.

S&B have put forward sufficient evidence to challenge the Mann et al analysis outcome and seriously weaken the IPCC assertions based on Mann et al. Paleo reconstruction of temperatures and the global pattern over the past millennium and longer remains a fertile field for research. It suggests that the climate system is such that a major temporal variation as is universally recognised for the European/North Atlantic region would be reflected globally and S&B have given support to this view.

It is my belief that the S&B work is a sincere endeavour to find out whether MWP and LIA were worldwide phenomena. The historical evidence beyond tree ring widths is convincing in my opinion. The concept of "Little Ice Age" is certainly used practically by all Holocene paleo-climatologists, who work on oblivious to Mann's "disproof" of its existence.

Paleoclimatologists tell me that, for debating purposes, they are more inclined to draw attention to the Holocene Optimum (about 6000 BP) as an undisputed example of climate about 1-2 deg C warmer than at present, and to ponder the entry and exit from the Younger Dryas as an example of abrupt climate change, than to get too excited about the Medieval Warm Period, which seems a very attenuated version. However, the Little Ice Age seems valid enough as a paleoclimatic concept. North American geologists repeatedly assert that the 19th century was the coldest century in North America since the LGM. To that extent, showing temperature increase since then is not unlike a mutual fund salesman showing expected rate of return from a market bottom - not precisely false, but rather in the realm of sleight-of-hand.

Chris

<x-flowed>

Hi Keith,

Thanks for the paper and help in toning down Mike's efforts to put a stake in the Esper heart. I quickly read the paragraph you mention. Undoubtedly part of what is said is true, but it doesn't explain it all of the differences between the original MBH reconstruction and any of the other NH recons. Now that Mike has moved on to a totally new NH recon, I suppose all of this is a mute point. However, your Blowing Hot and Cold piece clearly showed that the MBH estimates were undoubtedly deficient in low-frequency variability compared to ANY other recon. Enough said. I need to enjoy myself.

Cheers,

Ed

Dear fellow Eos co-authors,
Given the continued assault on the science of climate change by some
on Capitol Hill,
Michael and I thought it would be worthwhile to send this letter to
various members of the
U.S. Senate, accompanied by a copy of our Eos article.
Can we ask you to consider signing on with Michael and me (providing
your preferred title
and affiliation). We would like to get this out ASAP.
Thanks in advance,
Michael M and Michael O

Hi all - I'm not too comfortable with this, and would rather not sign
- at least not
without some real time to think it through and debate the issue. It is
unprecedented and
political, and that worries me.

My vote would be that we don't do this without a careful discussion
first.

I think it would be more appropriate for the AGU or some other
scientific org to do this -
e.g., in reaffirmation of the AGU statement (or whatever it's called)
on global climate
change.

Think about the next step - someone sends another letter to the
Senators, then we respond,
then...

I'm not sure we want to go down this path. It would be much better for
the AGU etc to do
it.

What are the precedents and outcomes of similar actions? I can imagine
a special-interest
org or group doing this like all sorts of other political actions, but
is it something for
scientists to do as individuals?

Just seems strange, and for that reason I'd advise against doing
anything with out real
thought, and certainly a strong majority of co-authors in support.

Cheers, Peck

<x-flowed>

Folks,

Here are some thoughts about the Soon issue, partly arising from talking to Ben.

What is worrying is the way this BS paper has been hyped by various groups. The publicity has meant that the work has entered the consciousness of people in Congress, and is given prominence in some publications emanating from that sector. The work appears to have the imprimatur of Harvard, which gives it added credibility.

So, what can we as a community do about this? My concerns are two-fold, and I think these echo all of our concerns. The first is the fact that the papers are simply bad science and the conclusions are incorrect. The second is that the work is being used quite openly for political purposes.

As scientists, even though we are aware of the second issue, we need to concentrate on exposing the scientific flaws. We also need to do this in as authoritative a way as possible. I do not think it is enough to speak as individuals or even as a group of recognized experts. Even as a group, we will not be seen as having the 'power' of the Harvard stamp of approval.

What I think is necessary is to have the expressed support of both AGU and AMS. It would also be useful to have Harvard disassociate themselves from the work. Most importantly, however, we need the NAS to come into the picture. With these 4 institutions, together with us (and others) as experts, pointing out clearly that the work is scientific rubbish, we can certainly win this battle.

I suggest that we try to get NAS to set up a committee to (best option) assess the science in the two BS papers, or (less good, but still potentially very useful) assess the general issue of the paleo record for global- or hemispheric-scale temperature changes over the past 1000 years. The second option seems more likely to be acceptable to NAS. This is arguably an issue of similar importance to the issue of climate sensitivity uncertainties which NAS reviewed earlier this year (report still in preparation).

I am not sure how to fold AGU and AMS into this -- ideas are welcome.

Similarly, perhaps some of you know some influential Harvard types better than I do and can make some suggestions here.

The only way to counter this crap is to use the biggest guns we can muster. The Administration and Congress still seem to respect the NAS (even above IPCC) as a final authority, so I think we should actively pursue this path.

Best wishes,
Tom.

From: "Michael E. Mann" <mann@virginia.edu>

To: Tim Osborn <t.osborn@uea.ac.uk>

Subject: Re: reconstruction errors

Date: Thu, 31 Jul 2003 11:18:24 -0400

Tim,

Attached are the calibration residual series for experiments based on available networks back to:

AD 1000

AD 1400

AD 1600

I can't find the one for the network back to 1820! But basically, you'll see that the residuals are pretty red for the first 2 cases, and then not significantly red for the 3rd case--its even a bit better for the AD 1700 and 1820 cases, but I can't seem to dig them up. In any case, the incremental changes are modest after 1600--its pretty clear that key predictors drop out before AD 1600, hence the redness of the residuals, and the notably larger uncertainties farther back...

You only want to look at the first column (year) and second column (residual) of the files. I can't even remember what the other columns are!

Let me know if that helps. Thanks,
mike

p.s. I know I probably don't need to mention this, but just to insure absolutely clarify on this, I'm providing these for your own personal use, since you're a trusted colleague. So please don't pass this along to others without checking w/ me first. This is the sort of "dirty laundry" one doesn't want to fall into the hands of those who might potentially try to distort things...

At 02:58 PM 7/31/2003 +0100, you wrote:

Thanks for the explanation, Mike. Now I see it, it looks familiar - so perhaps you've explained it to me previously (if you have, then sorry for asking twice!).

I now understand how you compute them in theory. I have two further questions though (sorry):

(1) how do you compute them in practise? Do you actually integrate the spectrum of the residuals?

(2) how would I estimate an uncertainty for a particular band of time scales (e.g. decadal to secular, $f=0.0$ to 0.1)? If integrating the spectrum of the residuals, I wonder whether integrating from $f=0$ to $f=0.02$ and then $f=0.02$ to (e.g.) $f=0.1$ (note this last limit has changed) would give me the right error for time scales of 10 years and longer (i.e. for a 10-yr low pass filter)? The way I had planned to do this was to assume the residuals could be modelled as a first order autoregressive process, with lag-1 autocorrelation $r_1=0.0$ after 1600 (essentially white) and $r_1=???$ before 1600. Do you know what the lag-1 autocorrelation of the residuals is for the network that goes

back to 1000 AD?

The stuff back 2000 years will be interesting, though the GCM runs we're starting to look at go back only 500 (Hadley Centre) or 1000 (German groups), so MBH99 seems fine for now.

Cheers

Tim

At 14:28 31/07/2003, you wrote:

Tim,

The one-sigma *total* uncertainty is determined from adding the low f and high f components of uncertainty in quadrature. The low f and high f uncertainties aren't uncertainties for a particular (e.g. 30 year or 40-year) running mean, they are band integrated estimates of uncertainties (high-frequency band from $f=0$ to $f=0.02$, low-frequency band from $f=0.02$ to $f=0.5$ cycle/year) taking into account the spectrum of the residual variance (the broadband or "white noise" mean of which is the nominal variance of the calibration residuals)

Alternatively, one could calculate uncertainties for a particular timescale average using the standard deviation of the calibration residuals, and applying a square-root-N' argument (where N' is the effective degrees of freedom in the calibration residuals). I believed I did this at one point, and got similar results.

Let me know if this needs further clarification. Thanks,
mike

p.s. you might want to try to using Mann and Jones N. Hem if you're going back further than AD 1000? Crowley has some EBM results now back to 0 AD, and is in the process of comparing w/ that. Sould be interesting...

At 02:04 PM 7/31/2003 +0100, you wrote:

Hi Mike,

we've recently been making plans with Simon Tett at the Hadley Centre for comparing model simulations with various climate reconstructions, including the MBH98 and MBH99 Northern Hemisphere temperatures. I was stressing the importance of including uncertainty estimates in the comparison and that the error estimates should depend on the timescale (e.g. smoothing filter or running mean) that had been applied.

I then looked at the file that I have been using for the uncertainties associated with MBH99 (see attachment), which I must have got from you some time ago. Column 1 is year, 2 is the "raw" standard error, 3 is $2*SE$.

But what are columns 4 and 5? I've been plotting column 4, labelled "1 sig (lowf)" when plotted your smoothed reconstruction, assuming that this is the error appropriate to low-pass filtered data. I'd also assumed that the last column "1 sig (highf)" was appropriate to high-pass filtered data. I also noticed that the sum of the squared high and low errors equalled the square of the raw error, which is nice.

But I've realised that I don't understand how you estimate these errors, nor what time scale the lowf and highf cutoff uses (maybe 40-year smoothed as in the IPCC plots?).

From MBH99 it sounds like post-1600 you assume uncorrelated gaussian calibration residuals. In which case you would expect the errors for a 40-year mean to be reduced by $\sqrt{40}$. This doesn't seem to match the values in the attached file. Pre-1600 you take into account that the residuals are autocorrelated (red noise rather than white), so presumably the reduction is less than $\sqrt{40}$, but some factor (how do you compute this?).

The reason for my questions is that I would like to (1) check whether I've been doing the right thing in using column 4 of the attached file with your smoothed reconstruction, and (2) I'd like to estimate the errors for a range of time scales, so I can compare decadal means, 30-year means, 50-year means etc.

Thanks in advance for any help you can give me here.

Subject: reconstruction errors
Date: Thu Jul 31 14:04:23 2003

Hi Mike,

we've recently been making plans with Simon Tett at the Hadley Centre for comparing model simulations with various climate reconstructions, including the MBH98 and MBH99 Northern Hemisphere temperatures. I was stressing the importance of including uncertainty estimates in the comparison and that the error estimates should depend on the timescale (e.g. smoothing filter or running mean) that had been applied.

I then looked at the file that I have been using for the uncertainties associated with MBH99 (see attachment), which I must have got from you some time ago. Column 1 is year, 2 is the "raw" standard error, 3 is $2*SE$.

But what are columns 4 and 5? I've been plotting column 4, labelled "1 sig (lowf)" when plotted your smoothed reconstruction, assuming that this is the error appropriate to low-pass filtered data. I'd also assumed that the last column "1 sig (highf)" was appropriate to high-pass filtered data. I also noticed that the sum of the squared high and low errors equalled the square of the raw error, which is nice.

But I've realised that I don't understand how you estimate these errors, nor what time scale the lowf and highf cutoff uses (maybe 40-year smoothed as in the IPCC plots?). From MBH99 it sounds like post-1600 you assume uncorrelated gaussian calibration residuals. In which case you would expect the errors for a 40-year mean to be reduced by $\sqrt{40}$. Thanks very much for helping me out with this Mike. Rest assured that the data won't be passed on to anyone else. I'll let you know if I use them to compute uncertainties at different time scales.

Cheers

Tim

At 16:18 31/07/2003, you wrote:

Tim,

Attached are the calibration residual series for experiments based on available networks back to:

AD 1000

AD 1400

AD 1600

I can't find the one for the network back to 1820! But basically, you'll see that the residuals are pretty red for the first 2 cases, and then not significantly red for the 3rd case--its even a bit better for the AD 1700 and 1820 cases, but I can't seem to dig them up. In any case, the incremental changes are modest after 1600--its pretty clear that key predictors drop out before AD 1600, hence the redness of the residuals, and the notably larger uncertainties farther back...

You only want to look at the first column (year) and second column (residual) of the files. I can't even remember what the other columns are!

Let me know if that helps. Thanks,
mike

p.s. I know I probably don't need to mention this, but just to insure absolutely clarify on this, I'm providing these for your own personal use, since you're a trusted colleague. So please don't pass this along to others without checking w/ me first. This is the sort of "dirty laundry" one doesn't want to fall into the hands of those who might potentially try to distort things...

Dear Jim,

Thanks for your continued interest and help w/ all this. It's nice to
know that our friends
down under are doing their best to fight the misinformation. It is
true that the skeptics
twist the truth clockwise rather than counterclockwise in the Southern
Hemisphere?

There was indeed a lot of activity last week. Hans Von Storch's
resignation as chief editor

of CR, which I think took a lot of guts, couldn't have come at a
better time. It was on the

night before before the notorious "James Inhofe", Chair of the Senate
"Environment and

Public Works Committee" attempted to provide a public stage for Willie
Soon and David

Legates to peddle their garbage (the Soon & Baliunas junk of course,
but also the usual

myths about the satellite record, 1940s-1970s cooling, "co2 is good
for us" and "but water
vapor is the primary greenhouse gas!").

Fortunately, these two are clowns, neither remotely as sharp as
Lindzen or as slick as

Michaels, and it wasn't too difficult to deal with them. Suffice it to
say, the event did

not go the way Inhofe and the republicans had hoped. The democrats,
conveniently, had

received word of Hans' resignation, but the republicans and
Soon/Legates had not. So when,

quite fittingly, Jim Jeffords (you may remember--he's the U.S. senator
who was in the news

a couple years ago for tilting the balance of power back to the
democrats when he left the

republican party in protest) hit them with this news at the hearing,
they were caught

completely off guard. The "Wall Street Journal" article you cited was
icing on the cake.

Inhofe, who rails against the liberal media, will have a difficult
time doing so against

the WSJ!

Also of interest to you (attached) might be the op-ed that Ray
Bradley, Phil, and I have

written and submitted to the "Seattle News Tribune" in response to an op-ed by Baliunas

(also attached) that some industry group has been sending around to various papers over the

last week. Only two (Providence Journal and Seattle NT) have thusfar bitten...

There is a rumour that Harvard may have had enough w/ their name being dragged through the

mud by the activities of Baliunas and Soon, and that "something is up". Baliunas and Soon,

as alluded to in the WSJ article, are now no longer talking to the media. Will keep you

posted on that...

mike

- >4) Internal-climate variability in the model -- ditto!
- >
- >3) & 4) I suggest we estimate from HadCM3 -- model var agrees well with
>paleo var so can't be too far wrong!

Yes, I'm happy that we use (3) and (4) from the model. If you use a short baseline to take the anomalies from, then the internal variability comes in twice in each case, both in comparing the baseline mean and the anomaly. We can minimise this by using a long baseline.

- >1) & 2) are, to some extent related, as calibration is estimate by
>regression -- thus minimising residual var (2). Nicest thing to do would
>be to estimate residual from indep. data but I don't think there is enough.....

The uncertainties that we've published with our regional and quasi-hemispheric reconstructions attempt to take both (1) and (2) in account already. Thus I use the standard errors on the two regression coefficients (for the linear regression of the sub-continental regions) and the standard errors on all multiple regression coefficients (for the quasi-Northern Hemisphere series). And then I incorporate the variance of the calibration residuals too (i.e., item (2)), modelled as first-order autoregressive terms. The appendix of the Briffa part 1 paper (page 755-757 is the appendix) in the Holocene special issue paper gives an explanation of this. Others quite often ignore (1) and just use the residuals to quantify reconstruction error, but (1) can be important especially for big anomalies (because the regression slope error is multiplied by the predicted anomaly). (1) can be difficult to quantify, of course, using some multi-variate techniques like Mann and Luterbacher use.

The regression standard errors (1) are of course computed from the calibration period. Our published errors also use the residual variance (2) computed from this calibration period. It is possible to compute (2) from independent data, but as you say we are limited by data. AND I think that the residual variance from independent data would also incorporate some or all of error (1) (because that would contribute to differences

between reconstruction and observation). I think it is better to keep the two terms separate and explicitly compute both, especially as their relative magnitudes can depend upon time scale (i.e., time averaging the data).

Am I right in thinking that the error in the *observed* record would, if taken into account, result in *reduced* reconstruction errors, because the residual variance (2) would not all be assumed to be reconstruction error - some would be observation error? But I suppose that the regression coefficient errors (1) would get larger to compensate? Anyway, we don't currently consider observed errors.

Cheers

Tim

dear all,
i think we all have seen [if not commented on] the devastating heat wave presently in europe - gives us a feeling on truly global warming. WWF has assured some money - a few thousand EUROS what is not much to be honest but at least a start - to ask an economist with climate policy understanding to assess in a short but fleshy paper [max 10 pages] the economic costs of these weather extremes in europe. This can be put in context with the mitigation costs of ambitious climate policies which are often quoted as a barrier to clean technologies unfortunately. I think, we as an NGO working on climate policy need such a document pretty soon for the public and for informed decision makers in order to get a) a debate started and b) in order to get into the media the context between climate extremes/desasters/costs and finally the link between weather extremes and energy - just the solutions parts what still is not communicated at all.
In short, can you advise us on a competent author who is readily available [can be one of you, of course], to bring together the conventionally accessible costs of reduced transport loads on rivers, in railway networks, forest fires, disruption of water supply and irrigation, closure of hydro power and even nuclear in some locations, health costs, agricultural failures [if accessible] etc etcetc...resulting from the heat wave?
Of course, i could not sent this e-mail to all competent sceintists, so fell free to share please and come back to me - at best ASAP

many regards

Andre,

I have been closely involved in the CR fiasco. I have had papers that I refereed (and soundly rejected), under De Freitas's editorship, appear later in the journal -- without me seeing any response from the authors. As I have said before to others, his strategy is first to use mainly referees that are in the anti-greenhouse community, and second, if a paper is rejected, to ignore that review and seek another more 'sympathic' reviewer. In the second case he can then (with enough reviews) claim that the honest review was an outlier.

I agree that an ethics committee is needed and I would be happy to serve on such a committee. It would have to have endorsement by international societies, like Roy. Soc., US Nat. Acad., Acad. Europ., plus RMS, AMS, AGU, etc.

Jim Titus mentioned to me that in the legal profession here people are disbarred for behavior like that of De Freitas (and even John Christy -- although this is a more subtle case). We cannot do that of course, but we can alert the community of honest scientists to such behavior and formally discredit these people.

The Danish Acad. did something like this recently, but were not entirely successful.

In the meantime, I urge people to dissociate themselves from Climate Research. The residual 'editorial' (a word I use almost tongue in cheek) board is looking like a rogues' gallery of skeptics. Those remaining who are credible scientists should resign.

Tom.

Tom,

I once met Soon at a meeting organised by the ESA in Tenerife. I think he gave a talk

-

but only think, so it wasn't memorable in any way. As you say they don't come to the regular meetings like EGU/S, AGU, AMS etc. I only went to Tenerife as the organisers paid for me to go.

Citation ratings vary (there are several different scales/indicators as well) a lot

from year to year for most journals. I've never figured out how the counting is done wrt

the highly cited lists that Tom. W., Kevin and I are on. Do only first authorships count for

example? Even with a common name like mine people still get it wrong and mistakes persist.

Surprisingly Jim Hansen doesn't make the above list ([1]<http://www.highlycited.com>), but then

he normally drops his E.

There are few more journals (QSR, Climate Change, IJC, AAR to give a few) where

paleo papers also appear.

Cheers

Phil

At 10:43 13/08/2003 -0400, Michael E. Mann wrote:

I checked this out prior to my senate hearing. Their science citations in the climate

literature are poor, as one would hope and expect.

Interestingly, they both drop their second initials when publishing in the climate

literature so that their names don't turn in up in ISI if you do a search on their

publications in the astronomy literature (which use the full initials)--apparently,

they don't want their astronomy colleagues to be aware that they're moonlighting as

supposed climatologists...

Their numbers are better in the astronomy literature, though Soon's numbers even here are mediocre.

Baliunas had some well-cited publications more than a decade ago. This is her work on the use of sun-like stars as a model for solar variability, etc., which is well

referenced in the astrophysics community. However, most of these appear to be her Ph.D.

work, and appear to have been published w/ her Ph.D adviser.

Not much evidence however that she has made any useful, independent contribution since

then. There are some additional papers she's published on time series analysis of solar

signals--looks like the kind of stuff you might expect to see from a graduate student

first-year research project....

In my opinion, its would be a mistake to evaluate these on their citations numbers in

astronomy. We should focus on their numbers in the climate literature, which are the

only ones relevant when discussing the issue of how their work on climate is received by

their fellow scientists,

mike

At 08:15 AM 8/13/2003 -0600, Tom Wigley wrote:

Might be interesting to see how frequently Soon and Baliunas, individually, are cited

(as astronomers). Are they any good in their own fields?

Perhaps we could start referring to them as astrologers (excusable as ... 'oops, just a typo')

Tom.

Tom Crowley wrote:

Hi there,

we need some data on Soon and Baliunas. one of my concerns is that they only publish in

low impact journals and completely bypass the normal give and take of presentations at

open scientific meetings (for example, I think I have probably heard 100 presentations

overall from the people on this mailing list).

it is therefore very important to inquire for the sake or our exchanges with

reporters/legislators etc as to how often any of you may have heard Soon or Baliunas

give a talk in an open meeting, where they could defend their analyses.

please respond to me as to whether you have heard either of them present something on

their paleo-analyses (I think I heard Baliunas speak once on her solar-type star work, but that doesn't count).

I will let you know the results of the poll so that we may all be on the same grounds

with respect to the data and reporting such information to press inquiries/legislators etc.

further fyi I list below the journal impact for six geophysical/climate/paleoclimate journals:

Paleoceanography 3.821
J. Climate 3.250
J. Geophysical Res. (Climate) 2.245
Geophysical Research Letters 2.150
The Holocene 1.852
Climate Research 1.016

Science and Nature are much higher (26-30) but their citation numbers are I believe

inflated with respect to our field because their citation ranking also includes many

very widely cited biology publications.

hope to hear from you soon, Tom

At 12:48 PM 8/22/2003 -0600, Tom Wigley wrote:

Mike,

Thanks for your clarifications.

With regard to the CO2 fertilization effect on tree ring width, I wrote a paper a number

of years ago pointing out that there were signal-to-noise problems in identifying and quantifying such factors.

Wigley, T.M.L., Jones, P.D. and Briffa, K.R., 1987: Detecting the effects of acidic

deposition and CO2-fertilization on tree growth. (In) Methods of Dendrochronology.

Vol. 1, Proceedings of the Task Force Meeting on Methodology of Dendrochronology:

Krak \leq w, Poland, 26 June 1986, (eds. L. Kairiukstis, Z. Bednarz and E. Feliksik),

International Institute for Applied Systems Analysis, Agricultural Academy of Krak \leq w,

Polish Academy of Science, WOSI Wsp \leq lna Sprawa 38/37 no. 20, 239253. 1988.

While I am confident that you are correct, and that this is not a crucial factor, I

think one should be careful about denying its existence. There are, furthermore,

additional obfuscating factors that make the effects of CO2 fertilization on ring widths

hard to identify.

Perhaps more important is the fact that many tree ring based reconstructions use density data, and the jury is still out on whether more CO2 increases or decreases density.

Tom.

Michael E. Mann wrote:

Dear Colleagues,

Several you have inquired about the below claims by the notorious "Idso brothers" which relates to the paper by Mann and Jones that appeared in GRL a couple weeks ago.

Of course, its the usual disinformation we've come to expect from these folks, but a few details on why:

1) The supposed "Co2 fertilization" argument is a ruse. The only evidence that such an effect might actually play some role in tree-growth trends has been found in high elevation sites in western North America (consult Malcolm Hughes for more details). As in Mann et al '99 (GRL), any such effect, to the extent it might exist, has been removed from the relevant series used in the latest (Mann and Jones) paper through the removal of anomalous differences between low-elevation and high-elevation western North American temperature trends during the post 1800 period, prior to use of the data in climate reconstruction.

2) We haven't in the past extended the proxy reconstruction beyond 1980 because many of the proxy data drop out. However, the repeated claim by the contrarians that post-1980 proxy data don't show the warming evident in the instrumental record has finally prompted me to go ahead and perform an additional analysis in which the proxy-reconstruction is extended forward as recently as at all possible (to 1995, for

which 3 out of 8 of the NH records are available, and 1 of the 5 SH records are available). The SH and GLB reconstructions are thus obviously tenuous at best, but they do address, to the extent at all possible, the issue as to whether or not the proxy reconstructions show the post-1980 warming--and they do.

See the attached plot which compares the NH (blue), SH (green), and GLB (red) series through 1995. The late 20th century is the nominal maximum for all 3 series *without any consideration of the information in the instrumental mean series*. This thus refutes

the 2nd criticism cited by the Idso brothers.
One note about the 40 year smoothing. As in the trends in the instrumental series shown by Mann and Jones, a boundary constraint on the 40-year smooth has been used that minimizes the 2nd derivative at the boundary--this trends to preserve the trend near the end of the series and has been argued as the optimal constraint in the present of nonstationary behavior near the end of a time series (Park, 1992; Ghil et al, 2002). I favor the use of this constraint in the smoothing of records that exhibit a significant trend as one approaches the end of the available data. This might be worth talking about in the next IPCC when the subject of adopting uniform standards for smoothing data, etc. are discussed...
In retrospect, Phil and I should have included this analysis in the GRL article, but its always hard to know what specifics the contrarians are going to target in their attacks.
This analysis however, will be included in a review paper by Jones and Mann on "climate in past millennia" that is presently being finalized for "Reviews of Geophysics".
I hope that helps clarify any questions any of you might have had. Please feel free to pass this information along to anyone who might benefit from it.
Now, back to fighting the "Shaviv and Veizer" propaganda along w/ Ben Santer and David Parker out in Italy...
mike

Dear all,
GRL finally published the study
Mann, Michael E. and Phil D. Jones, 2003. Global surface temperatures

over the past two millennia, Geophysical Research Letters Vol. 30,
No.

15, 1820, 10.1029/2003GL017814, August 14, 2003

Abstract

[1] We present reconstructions of Northern and Southern Hemisphere mean surface temperature over the past two millennia based on high-resolution ?proxy? temperature data which retain millennial-scale

variability. These reconstructions indicate that late 20th century warmth is unprecedented for at least roughly the past two millennia for

the Northern Hemisphere. Conclusions for the Southern Hemisphere and global mean temperature are limited by the sparseness of available

proxy data in the Southern Hemisphere at present.

We already noticed the study in

Mann, Michael, Caspar Ammann, Kevin Trenberth, Raymond Bradley, Keith

Briffa, Philip Jones, Tim Osborn, Tom Crowley, Malcolm Hughes, Michael

Oppenheimer, Jonathan Overpeck, Scott Rutherford, and Tom Wigley, 2003.

On Past Temperatures and Anomalous Late-20th Century Warmth. Eos, Vol.

84, No. 27, page 256, July 8, 2003

There we found that " an extension back through the past 2000 years based on eight long reconstructions [Mann and Jones,2003]."

CO2 Science Magazine today presents the study as follows:

Was Late 20th Century Warming Really Unprecedented Over the Past Two Millennia?

Mann, M.E. and Jones, P.D. 2003. Global surface temperatures over the

past two millennia. Geophysical Research Letters 30:
10.1029/2003GL017814.

What was done

Using 23 individual proxy records from 8 distinct regions in the Northern Hemisphere and 5 proxy records from the Southern Hemisphere,

the authors constructed Northern and Southern Hemispheric and global mean temperature histories over the period AD 200 to as close as

they could get to the present employing a 40-year lowpass filter of the data.

What was learned

Mann and Jones say their temperature reconstructions indicate that "late

20th century warmth is unprecedented for at least roughly the past two

millennia for the Northern Hemisphere." They also say their data

and analysis "suggest a similar, but less definitive conclusion, for the global mean."

Although we and many others have many bones to pick with many aspects of

Mann and Jones' analysis, we will here focus on just a couple of points and temporarily grant them the benefit of the doubt in those other areas. First of all, granting them almost everything they have done, it can readily be seen from their own graph of their own results that the point of their reconstructed global mean temperature history is not the warmest period of the prior 1800 years. In fact, their treatment of the data depicts three earlier warmer periods: one just prior to AD 700, one just after AD 700 and one just prior to AD 1000 (see figure below). Reconstructed global temperature anomaly (based on 1961-1990 instrumental reference period) adapted from Mann and Jones (2003). The globe only becomes warmer in the 20th century when its measured temperatures are substituted for its reconstructed temperatures.

This approach is clearly unacceptable; it is like comparing apples and oranges. If one has only reconstructed temperatures from the distant past, one can only validly compare them with reconstructed temperatures from the recent past.

Another important point that is ignored by Mann and Jones is that the last century witnessed a dramatic increase in atmospheric CO2 concentration, which everyone knows is an effective aerial fertilizer.

It also witnessed a dramatic increase in atmospheric nitrogen deposition, which further enhances plant growth. Consequently, as tree-ring data comprise the bulk of the proxy temperature information employed by Mann and Jones, their reconstructed global mean temperature history must possess a non-temperature-induced pseudo-warming signal driven by CO2- and nitrogen-induced increases in growth that make 20th century warming appear significantly greater than it really is.

Hence, there could well be still other periods of the past 1800 years (in addition to the three we have already noted) when the global mean temperature was also warmer than it was at the end of their reconstructed record in the 20th century.

What it means Mann and Jones have clearly failed to demonstrate the key point they desired to make in their paper. Their data, however, speak for themselves in clearly demonstrating that late 20th century warmth was not unprecedented over the past two millennia.

????
We have already discussed about this study in July under title ?Empire

Strikes back on Soon et al.? |

Attachments: Mann uncertainty.doc

Hi Mike,

after a few bits of holiday here and there, I've now had time to complete my (initial) approach to estimating reconstruction errors on your NH temperature reconstruction. This is all based on the calibration residuals that you kindly sent me a few weeks ago.

My rationale for doing this was that I wanted uncertainty/error estimates that were dependent on the time scale being considered (e.g. a decadal mean, an annual mean, a 30-year mean, etc.). I didn't think you had published timescale-dependent errors, hence my attempt.

A second reason is that I wanted to be able to model (i.e., stochastically generate) time series of the errors, with appropriate timescale characteristics. Again, I didn't think that I could get this from your published results.

The attached document summarises the progress I've made. There are a few questions I have, and I'm concerned that the reduction in uncertainty with increasing time scale is too great. Perhaps one should be ultra conservative and have no reduction with time scale? Yet surely there ought to be some cancelling of partly uncorrelated errors? The document is not meant to form part of any paper on this (I hope to use the errors in a paper, but the point of the paper is on trend detection, not estimating errors), it just seemed appropriate to write it up like this to inform you of what I've done so far.

Any comments or criticisms will be very useful.

Cheers

Tim

Hi Tim

Thanks for sending this. Unfortunately, I don't really have the time to look into any of this in detail, but let me offer the following additional explanation which will hopefully clarify the nature of any differences between our results. I fear that I may not have been clear enough in my previous explanation.

The reason that our uncertainty estimates reduce little with increasing timescale for the earlier networks is that the effective degrees of freedom are diminished sharply by the redness of the calibration residuals for networks prior to AD 1600 and earlier. But unlike you, we do not model the residuals as an AR process--this may be the source of some of the differences.

Back to AD 1600 (and later networks), the calibration residuals pass for "white noise", and the estimates follow simply from the residual uncalibrated variance, and the reduction of variance upon averaging follows standard \sqrt{N} statistics.

Prior to that, the networks failed the test. So we decomposed the calibration residuals into a "low-frequency" band (all timescales longer than 40 years which are not distinguishable from secular timescales, since I had a roughly 80 year series and was evaluating the spectrum using a multiple-taper estimate with a spectral bandwidth of ± 2 Rayleigh frequencies). We then estimated the enhancement of unresolved variance in the low-frequency band relative to the nominal white noise level. The enhancement was about a factor of 5-6 or so for the earlier networks, as I recall. To get the component of uncertainty for the low-frequency band alone (timescales longer than 40 years), I simply took that enhancement factor \times the nominal unresolved calibration variance \times the bandwidth of the "low-frequency" band (0.025 cycle/year). This yields a reduction in variance that is far less than the nominal " \sqrt{N} " reduction applied to the individual annual uncertainties. Of course, one could calculate the equivalent N' (effective temporal degrees of freedom) that this implies in a model of the residuals as AR(1) red noise, but we didn't take this approach. We modeled it as a simple step-increase spectrum (with the boundary at $f=0.025$ cycle/yr). Modeling the residuals as red noise would, my guess is, generally yield the same result, but it might have the effect of dampening the estimated enhancement of unresolved variance at the longest timescales. In any case, it should yield similar, but it would be very surprising if identical(!), results, consistent with your observations.

My guess for the difference in the AD 1600 network is that, based on the spectrum test, we did not reject the white noise null hypothesis for the residuals. So there was no variance enhancement factor for that, or subsequent, networks. It would appear that your method argues for significant serial correlation in that case. Not sure why we come to different

conclusions in this case (perhaps using different criteria for testing for the significance of redness in the spectrum/serial correlation), but that's probably the reason...

I hope that clarifies this. Please keep me in the loop on this. I've copied to Scott, who may have some additional insights here, since we've been dealing w/ these issues now in the RegEM estimates (Scott:did we ever reject the white noise null hypothesis in the residuals for any of our proxy-based NH reconstructions in the paper submitted to J. Climate? I don't recall).

Thanks,
mike

My rationale for doing this was that I wanted uncertainty/error estimates that were dependent on the time scale being considered (e.g. a decadal mean, an annual mean, a 30-year mean, etc.). I didn't think you had published timescale-dependent errors, hence my attempt.

A second reason is that I wanted to be able to model (i.e., stochastically generate) time series of the errors, with appropriate timescale characteristics. Again, I didn't think that I could get this from your published results.

The attached document summarises the progress I've made. There are a few questions I have, and I'm concerned that the reduction in uncertainty with increasing time scale is too great. Perhaps one should be ultra conservative and have no reduction with time scale? Yet surely there ought to be some cancelling of partly uncorrelated errors? The document is not meant to form part of any paper on this (I hope to use the errors in a paper, but the point of the paper is on trend detection, not estimating errors), it just seemed appropriate to write it up like this to inform you of what I've done so far.

Any comments or criticisms will be very useful.

Cheers

Tim

Subject: An idea to pass by you
Date: Wed, 3 Sep 2003 08:32:11 -0400

<x-flowed>

Hi Keith,

After the meeting in Norway, where I presented the Esper stuff as described in the extended abstract I sent you, and hearing Bradley's follow-up talk on how everybody but him has fucked up in reconstructing past NH temperatures over the past 1000 years (this is a bit of an overstatement on my part I must admit, but his air of papal infallibility is really quite nauseating at times), I have come up with an idea that I want you to be involved in. Consider the tentative title:

"Northern Hemisphere Temperatures Over The Past Millennium: Where Are The Greatest Uncertainties?"

Authors: Cook, Briffa, Esper, Osborn, D'Arrigo, Bradley(?), Jones(??), Mann (infinite?) - I am afraid the Mike and Phil are too personally invested in things now (i.e. the 2003 GRL paper that is probably the worst paper Phil has ever been involved in - Bradley hates it as well), but I am willing to offer to include them if they can contribute without just defending their past work - this is the key to having anyone involved. Be honest. Lay it all out on the table and don't start by assuming that ANY reconstruction is better than any other.

Here are my ideas for the paper in a nutshell (please bear with me):

- 1) Describe the past work (Mann, Briffa, Jones, Crowley, Esper, yada, yada, yada) and their data over-laps.
- 2) Use the Briffa&Osborn "Blowing Hot And Cold" annually-resolved recons (plus Crowley?) (boreholes not included) for comparison because they are all scaled identically to the same NH extra-tropics temperatures and the Mann version only includes that part of the NH (we could include Mann's full NH recon as well, but he would probably go ballistic, and also the new Mann&Jones mess?)

- 3) Characterize the similarities between series using unrotated (maybe rotated as well) EOF analysis (correlation for pure similarity, covariance for differences in amplitude as well) and filtering on the reconstructions - unfiltered, 20yr high-pass, 100-20 bandpass, 100 lowpass - to find out where the reconstructions are most similar and different - use 1st-EOF loadings as a guide, the comparisons of the power spectra could also be done I suppose
- 4) Do these EOF analyses on different time periods to see where they differ most, e.g., running 100-year EOF windows on the unfiltered data, running 300-year for 20-yr data (something like that anyway), and plot the 1st-EOF loadings as a function of time
- 5) Discuss where the biggest differences lie between reconstructions (this will almost certainly occur most in the 100 lowpass data), taking into account data overlaps
- 6) Point out implications concerning the next IPCC assessment and EBM forcing experiments that are basically designed to fit the lower frequencies - if the greatest uncertainties are in the >100 year band, then that is where the greatest uncertainties will be in the forcing experiments
- 7) Publish, retire, and don't leave a forwarding address

Without trying to prejudice this work, but also because of what I almost think I know to be the case, the results of this study will show that we can probably say a fair bit about <100 year extra-tropical NH temperature variability (at least as far as we believe the proxy estimates), but honestly know fuck-all about what the >100 year variability was like with any certainty (i.e. we know with certainty that we know fuck-all).

Of course, none of what I have proposed has addressed the issue of seasonality of response. So what I am suggesting is strictly an empirical comparison of published 1000 year NH reconstructions because many of the same tree-ring proxies get used in both seasonal and annual recons anyway. So all I care about is how the recons differ and where they differ most in frequency and time without any direct consideration of their TRUE association with observed temperatures.

I think this is exactly the kind of study that needs to be done

before the next IPCC assessment. But to give it credibility, it has to have a reasonably broad spectrum of authors to avoid looking like a biased attack paper, i.e. like Soon and Balliunas.

If you don't want to do it, just say so and I will drop the whole idea like a hot potato. I honestly don't want to do it without your participation. If you want to be the lead on it, I am fine with that too.

Cheers,

Ed

Subject: Fwd: Re: Fwd: Soon & Baliunas
Date: Wed Sep 3 15:54:41 2003

Hi Ed,
first all, yes I agree that we need a paper that takes a more objective look at where we are now and how we can take things forward in terms of NH temperature reconstructions (and possibly global, SH, spatial etc.).

As Keith said, we (mainly I so far) have been planning our version of this (hopefully) "objective assessment", and by chance I was sketching out a vague outline of its possible content. We've been keeping this fairly close to our chests for now, so please keep our plans/ideas to yourself for the moment. There is partial overlap between our ideas and yours, so it might be good to do this jointly. Anyway, my current ideas are a number of forum articles, the first comparing existing reconstructions but without going into more depth, and the other three looking at the way forward (i.e. what should we attempt to do to improve them):

Forum piece (1): Comparison of existing reconstructions

This has most overlaps with your ideas, though I hadn't thought of it being so comprehensive. I was thinking more of:

- (a) comparing original series.
- (b) comparing them after our recalibration to common target data, including discussion of why some things don't change much (e.g. relative positioning of reconstructions), though amplitudes can change - and of course the comparison of Mann et al. with and without oceans/tropics.
- (c) maybe a bit on comparison with boreholes, though maybe not.
- (d) uncertainty estimates and how these may decrease with time scale and hence not all reconstructions lie in the Mann et al. uncertainty ranges.

Forum piece (2): Selection of predictand and predictor data

- (a) What to try to reconstruct and why it matters - e.g. will we get the wrong spectral shape if we reconstruct ocean SST from land-based proxies. Plus some on seasonality, though Jones, Osborn and Briffa cover part of that issue (are you aware of that paper, in press with JGR?).
- (b) What proxies should be used - e.g. does throwing in "poor" proxies cause a problem with simple averaging, weighted averaging and multivariate regression approaches. Plus does using precipitation proxies to reconstruct temperature result in the wrong spectral shape?

Forum piece (3): Reconstruction methods

Something here on different methods (simple averaging, multivariate regression type approaches) and different implementation choices (e.g. calibration against trends/filtered data). Not entirely sure about this, but it would not be new work, just would critically appraise the methods used to date and what their theoretical/potential problems/advantages might be.

Forum piece (4): Estimating uncertainty

Again, not entirely sure yet, but this must emphasise the absolute requirement to estimate AND USE uncertainty when comparing reconstructions against observations or simulations etc. Then something about how to do it, contrasting using calibration residuals, verification residuals, parameter uncertainty, with the type of approach that you've taken (bootstrap uncertainty, or measures of the EPS) to look at the common signal, with additional uncertainty of how the common signal differs from the predictand.

So that's it!! Perhaps rather ambitious, so maybe a reduction to certain key points might be required. I was deliberately avoiding any review of tree-ring contributions and low-frequency per se, thinking that you and Keith would be taking the lead on that kind of review.

One final think to mention, is that the emails copied below and the attached file might be of interest to you as an example of something that *might* go in a comparison paper of existing reconstructions. It's shows how the recalibrated average of existing reconstructions differs from the average of existing calibrated reconstructions. You'll see from Mike Mann's initial request below that he was thinking of it as a contribution to the EOS rebuttal of Soon and Baliunas, but I've not heard much from him since. Also Tom Crowley was very interests in this composite of the reconstructions, and I started to converse with him about it but never finished estimating the uncertainty range on the composite series and kind of stopped emailing him. But I guess either of them might reproduce this idea sometime, if it suits them.

A visit to talk face to face about all these things would be good. Keith and I have been talking about how to fit a visit in.

Cheers

Tim

To: "Michael E. Mann" <mann@virginia.edu>, Tom Crowley <tcrowley@duke.edu>, Phil Jones <p.jones@uea.ac.uk>

From: Tim Osborn <t.osborn@uea.ac.uk>

Subject: Re: Fwd: Soon & Baliunas

Cc: Malcolm Hughes <mhughes@ltrr.arizona.edu>, rbradley@geo.umass.edu, mhughes@ltrr.arizona.edu, srutherford@gso.uri.edu, k.briffa@uea.ac.uk, mann@virginia.edu

This is an excellent idea, Mike, IN PRINCIPLE at least. In practise, however, it raises some interesting results (as I have found when attempting this myself) that may be difficult to avoid getting bogged down with discussing.

The attached .pdf figure shows an example of what I have produced (NB. please don't circulate this further, as it is from work that is currently being finished off - however, I'm happy to use it here to illustrate my point).

I took 7 reconstructions and re-calibrated them over a common period and against an observed target series (in this case, land-only, Apr-Sep, >20N - BUT I GET SIMILAR RESULTS WITH OTHER CHOICES, and this re-calibration stage is not critical). You will have seen figures similar to this in stuff Keith and I have published. See the coloured

lines in the attached figure.

In this example I then simply took an unweighted average of the calibrated series, but the weighted average obtained via an EOF approach can give similar results. The average is shown by the thin black line (I've ignored the potential problems of series covering different periods). This was all done with raw, unsmoothed data, even though 30-yr smoothed curves are plotted in the figure.

The thick black line is what I get when I re-calibrate the average record against my target observed series. **THIS IS THE IMPORTANT BIT.** The **re-calibrated** mean of the reconstructions is nowhere near the mean of the reconstructions. It has enhanced variability, because averaging the reconstructions results in a redder time series (there is less common variance between the reconstructions at the higher frequencies compared with the lower frequencies, so the former averages out to leave a smoother curve) and the re-calibration is then more of a case of fitting a trend (over my calibration period 1881-1960) to the observed trend. This results in enhanced variability, but also enhanced uncertainty (not shown here) due to fewer effective degrees of freedom during calibration.

Obviously there are questions about observed target series, which series to include/exclude etc., but the same issue will arise regardless: the analysis will not likely lie near to the middle of the cloud of published series and explaining the reasons behind this etc. will obscure the message of a short EOS piece.

It is, of course, interesting - not least for the comparison with borehole-based estimates - but that is for a separate paper, I think.

My suggestion would be to stick with one of these options:

- (i) a single example reconstruction;
- (ii) a plot of a cloud of reconstructions;
- (iii) a plot of the "envelope" containing the cloud of reconstructions (perhaps also the envelope would encompass their uncertainty estimates), but without showing the individual reconstruction best guesses.

How many votes for each?

Cheers

Tim

At 15:32 12/03/03, Michael E. Mann wrote:

p.s. The idea of both a representative time-slice spatial plot emphasizing the spatial variability of e.g. the MWP or LIA, and an EOF analysis of all the records is a great idea. I'd like to suggest a small modification of the latter:

I would suggest we show 2 curves, representing the 1st PC of two different groups, one of empirical reconstructions, the other of model simulations, rather than just one in the time plot.

Group #1 could include:

- 1) Crowley & Lowery
- 2) Mann et al 1999
- 3) Bradley and Jones 1995

4) Jones et al, 1998

5) Briffa et al 200X? [Keith/Tim to provide their preferred MXD reconstruction]

6) Esper et al [yes, no?--one series that differs from the others won't make much of a difference]

I would suggest we scale the resulting PC to the CRU 1856-1960 annual Northern Hemisphere mean instrumental record, which should overlap w/ all of the series, and which pre-dates the MXD decline issue...

Group #2 would include various model simulations using different forcings, and with slightly different sensitivities. This could include 6 or so simulation results:

1) 3 series from Crowley (2000) [based on different solar/volcanic reconstructions],

2) 2 series from Gerber et al (Bern modeling group result) [based on different assumed sensitivities]

1) Bauer et al series (Claussen group EMIC result) [includes 19th/20th century land use changes as a forcing].

I would suggest that the model's 20th century mean is aligned with the 20th century instrumental N.Hem mean for comparison (since this is when we know the forcings best).

I'd like to nominate Scott R. as the collector of the time series and the performer of the EOF analyses, scaling, and plotting, since Scott already has many of the series and many of the appropriate analysis and plotting tools set up to do this.

We could each send our preferred versions of our respective time series to Scott as an ascii attachment, etc.

thoughts, comments?

thanks,

mike

At 10:08 AM 3/12/2003 -0500, Michael E. Mann wrote:

Thanks Tom,

Either would be good, but Eos is an especially good idea. Both Ellen M-T and Keith Alverson are on the editorial board there, so I think there would be some receptiveness to such a submission.

I see this as complementary to other pieces that we have written or are currently writing (e.g. a review that Ray, Malcolm, and Henry Diaz are doing for Science on the MWP) and this should proceed entirely independently of that.

If there is group interest in taking this tack, I'd be happy to contact Ellen/Keith about the potential interest in Eos, or I'd be happy to let Tom or Phil to take the lead too...

Comments?

mike

At 09:15 AM 3/12/2003 -0500, Tom Crowley wrote:

Phil et al,

I suggest either BAMS or Eos - the latter would probably be better because it is shorter, quicker, has a wide distribution, and all the points that need to be made have been made before.

rather than dwelling on Soon and Baliunas I think the message should be pointedly made against all of the standard claptrap being dredged up.

I suggest two figures- one on time series and another showing the spatial array of temperatures at one point in the Middle Ages. I produced a few of those for the Ambio paper but already have one ready for the Greenland settlement period 965-995 showing the regional nature of the warmth in that figure. we could add a few new sites to it, but if people think otherwise we could of course go in some other direction.

rather than getting into the delicate question of which paleo reconstruction to use I suggest that we show a time series that is an eof of the different reconstructions - one that emphasizes the commonality of the message.

Tom

Dear All,

I agree with all the points being made and the multi-authored article would be a good idea, but how do we go about not letting it get buried somewhere. Can we not address the misconceptions by finally coming up with definitive dates for the LIA and MWP and redefining what we think the terms really mean? With all of us and more on the paper, it should carry a lot of weight. In a way we will be setting the agenda for what should be being done over the next few years.

We do want a reputable journal but is The Holocene the right vehicle. It is probably the best of its class of journals out there. Mike and I were asked to write an article for the EGS journal of Surveys of Geophysics. You've not heard of this - few have, so we declined. However, it got me thinking that we could try for Reviews of Geophysics. Need to contact the editorial board to see if this might be possible. Just a thought, but it certainly has a high profile.

What we want to write is NOT the scholarly review a la Jean Grove (bless her soul) that

just reviews but doesn't come to anything firm. We want a critical review that enables agendas to be set. Ray's recent multi-authored piece goes a lot of the way so we need to build on this.

Cheers

Phil

At 12:55 11/03/03 -0500, Michael E. Mann wrote:

Hi Malcolm,

Thanks for the feedback--I largely concur. I do, though, think there is a particular problem with "Climate Research". This is where my colleague Pat Michaels now publishes exclusively, and his two closest colleagues are on the editorial board and review editor board. So I promise you, we'll see more of this there, and I personally think there **is** a bigger problem with the "messenger" in this case...

But the Soon and Baliunas paper is its own, separate issue too. I too like Tom's latter idea, of a more hefty multi-authored piece in an appropriate journal (Paleoceanography? Holocene?) that seeks to correct a number of misconceptions out there, perhaps using Baliunas and Soon as a case study ('poster child?'), but taking on a slightly greater territory too.

Question is, who would take the lead role. I **know** we're all very busy,
mike

At 10:28 AM 3/11/03 -0700, Malcolm Hughes wrote:

I'm with Tom on this. In a way it comes back to a rant of mine to which some of you have already been victim. The general point is that there are two arms of climatology:

neoclimatology - what you do based on instrumental records and direct, systematic observations in networks - all set in a very Late Holocene/Anthropocene time with hourly to decadal interests.

paleoclimatology - stuff from rocks, etc., where major changes in the Earth system, including its climate, associated with major changes in boundary conditions, may be detected by examination of one or a handful of paleo records.

Between these two is what we do - "mesoclimatology" - dealing with many of the same phenomena as neoclimatology, using documentary and natural archives to look at phenomena on interannual to millennial time scales. Given relatively small changes in boundary conditions (until the last couple of centuries), mesoclimatology has to work in a way that is very similar to neoclimatology. Most notably, it depends on heavily replicated networks of precisely dated records capable of being either calibrated, or whose relationship to climate may be modeled accurately and precisely.

Because this distinction is not recognized by many (e.g. Sonnechkin, Broecker, Karlen) we see an accumulation of misguided attempts at describing the climate of recent millennia. It would be better to head this off in general, rather than draw attention to a bad paper. After all, as Tom rightly says, we could all nominate really bad papers that have been published in journals of outstanding reputation (although there could well be differences between our lists).

End of rant, Cheers, Malcolm

sorry phil, one more relevant item. I've cc'd in Keith on this, since you had mentioned that you had discussed the issue w/ him.

This is from Dave Meko's (quite nice!) statistics lecture notes:

[1]http://www.ltrr.arizona.edu/~dmeko/notes_8.pdf

See page 2, section 8.1.

He provides two (in reality, as I mentioned before, there are really 3!) basic boundary constraints on a smooth (ie, in "filtering"). The first method he refers to is what I called the "minimum norm" constraint (assuming the long-term mean beyond the boundary). The second, which he calls "reflecting the data across the endpoints", is the constraint I have been employing which, again, is mathematically equivalent to insuring a point of inflection at the boundary. This is the preferable constraint for non-stationary mean processes, and we are, I assert, on very solid ground (preferable ground in fact) in employing this boundary constraint for series with trends...

mike

Mike,

Attached some more plots.

1. Figure 7 - Forcing. Guess this is it. Could cut the y scale to -6 and say in caption that

1258 or 1259 is the only event to go beyond this, then give value in caption. Scale will then widen out. OK to do ? Caspar's solar now there.

2. Fig 2a - first go at coverage. This is % coverage over 1856-2002 from HadCRUT2v.

3. Fig 4 again. Moved legends and reduced scale. Talked to Keith and we both think that

the linear trend padding will get criticised. Did you use this in GRL and or Fig 5 for RoG

with Scott. If so we need to explain it.

On this plot all the series are in different units, so normalised over 1751-1950 (or equiv for

decades) then smoothed. Again here I can reduce scale further and Law Dome can go out of the plot. Thoughts ? Think all should be same scale.

Have got GKSS model runs for Fig 8. Were you happy Hans' conditions. If so I'll send onto

Scott.

Next week I only have Fig 2b to do. This will be annual plot of NH, Europe and CET, smoothed in some way.

For the SOI I and Tim reckon that it won't work showing this at interannual timescale with

3 plots. It will then not be like the NAO plot.

Thoughts on colours as well.

Have a good weekend. Logging off once this has gone.

Cheers

Phil

sorry, meant "is just the minimum slope" constraint, in first sentence...
apologies for the multiple emails,
mike

At 01:47 PM 9/5/2003 -0400, Michael E. Mann wrote:

Actually,

I think Dave's suggestion "reflecting the data across the endpoints" is really just the "minimum norm" constraint, which insures zero slope near the boundary. In other words, he's probably only talking about reflecting about the time axis. I assert that a preferable alternative, when there is a trend in the series extending through the boundary is to reflect both about the time axis and the amplitude axis (where the reflection is with respect to the y value of the final data point). This insures a point of inflection to the smooth at the boundary, and is essentially what the method I'm employing does (I simply reflect the trend but not the variability about the trend--they are almost the same)...

mike

sorry phil, one more relevant item. I've cc'd in Keith on this, since you had mentioned that you had discussed the issue w/ him.

This is from Dave Meko's (quite nice!) statistics lecture notes:

[1]http://www.ltrr.arizona.edu/~dmeko/notes_8.pdf

See page 2, section 8.1.

He provides two (in reality, as I mentioned before, there are really 3!) basic boundary constraints on a smooth (ie, in "filtering"). The first method he refers to is what I called the "minimum norm" constraint (assuming the long-term mean beyond the boundary). The second, which he calls "reflecting the data across the endpoints", is the constraint I have been employing which, again, is mathematically equivalent to insuring a point of inflection at the boundary. This is the preferable constraint for non-stationary mean processes, and we are, I assert, on very solid ground (preferable ground in fact) in employing this boundary constraint for series with trends...

<x-flowed>

Dear All,

Link below is to a paper just out in the US. Could be some press coverage - as it says

there is no difference between urban and rural stations for temperature over the US !

Interesting to see if the skeptics pick up on this. They are probably still going through the

Vinnikov/Grody paper in Science showing MSU2 warming more than the surface, so

they have a lot to look at.

I reviewed Peterson's one with Chris and couldn't see anything wrong with the main message.

Cheers

Phil

Subject: COLD season T reconstruction
Date: Tue, 30 Sep 2003 14:24:57 +0200
Reply-to: f14@zedat.fu-berlin.de

Hi Tim, hi Keith,

attached you can find my reconstruction of the cold season temperature anomalies. I have retained the 3rd, 4th, 5th and 6th EOFs for the whole time span (1500-1976). It seems to be a rather strange choice, but if I retain the 1st and/or 2nd EOFs the reconstructed T anomalies for Northern Europe are too large in comparison to observed anomalies. You will see that calibration/verification skills are miserable. But it puts my mind to rest, if you say, that this is an expected result.

Last week you wrote :

>Please let us (me and Keith) know if you are happy with your implementation
>of the Mann et al. method. I remember that you had some strange results
>when you applied it to the model simulations - did you solve those
>problems? We might be able to help or provide advice if you still have
>problems with the method.

The problems I mentioned at the meeting in France arose if I applied my implementation of the method to the INSTRUMENTAL data and I tried to explain this effect through the gaps in the data. In the meantime I was able to eliminate to some degree this problem through the use of other fortran compiler and numeric library. I will prepare an slide with assesment of the performance of the current method implementation for "perfect proxy data" (i.e. instrumental data as proxy data).

And now some words to agenda

- 1) Antje Weisheimer will say initial greeting words and make all organisational announcements.
- 2) As you know, Ulrich take part in the analysis of the simulations performed with ECHO-G by GKSS group. I am not sure, but maybe he will also present his ideas for further (in framework of SO&P reasonable) simulations, that can be conducted by FUB.

For the presentations both OHP and data projector are available.

Dear Mr. Matthews,

Unfortunately Phil Jones is travelling and will probably be unable to offer a separate reply. Since your comments involve work that is his as well, I have therefore taken the liberty of copying your inquiry and this reply to several of his British colleagues.

The comparisons made in our paper are well explained therein, and your statements belie the clearly-stated qualifications in our conclusions with regard to separate analyses of the Northern Hemisphere, Southern Hemisphere, and globe.

An objective reading of our manuscript would readily reveal that the comments you refer to are scurrilous. These comments have not been made by scientists in the peer-reviewed literature, but rather, on a website that, according to published accounts, is run by individuals sponsored by ExxonMobile corporation, hardly an objective source of information.

Owing to pressures on my time, I will not be able to respond to any further inquiries from you. Given your extremely poor past record of reporting on climate change issues, however, I will leave you with some final words. Professional journalists I am used to dealing with do not rely upon un-peer-reviewed claims off internet sites for their sources of information. They rely instead on peer-reviewed scientific research, and mainstream, rather than fringe, scientific opinion.

Sincerely,

Michael E. Mann

For those of you who haven't seen it, this is Robert Matthews last article on the topic.

Hence the fairly brusque tone taken...

mike

Middle Ages were warmer than today, say scientists

By Robert Matthews, Science Correspondent

(Filed: 06/04/2003)

Claims that man-made pollution is causing "unprecedented"

global warming

have been seriously undermined by new research which shows that the

Earth

was warmer during the Middle Ages.

From the outset of the global warming debate in the late 1980s,

environmentalists have said that temperatures are rising higher and

faster

than ever before, leading some scientists to conclude that greenhouse

gases

from cars and power stations are causing these

"record-breaking" global

temperatures.

Last year, scientists working for the UK Climate Impacts Programme said

that

global temperatures were "the hottest since records began"

and added: "We

are pretty sure that climate change due to human activity is here and

it's

accelerating."

This announcement followed research published in 1998, when scientists

at

the Climatic Research Unit at the University of East Anglia declared

that

the 1990s had been hotter than any other period for 1,000 years.

Such claims have now been sharply contradicted by the most

comprehensive

study yet of global temperature over the past 1,000 years. A review of

more

than 240 scientific studies has shown that today's temperatures

are neither

the warmest over the past millennium, nor are they producing the most

extreme weather - in stark contrast to the claims of the

environmentalists.

The review, carried out by a team from Harvard University, examined the findings of studies of so-called "temperature proxies" such as tree rings, ice cores and historical accounts which allow scientists to estimate temperatures prevailing at sites around the world.

The findings prove that the world experienced a Medieval Warm Period between the ninth and 14th centuries with global temperatures significantly higher even than today.

They also confirm claims that a Little Ice Age set in around 1300, during which the world cooled dramatically. Since 1900, the world has begun to warm up again - but has still to reach the balmy temperatures of the Middle Ages.

The timing of the end of the Little Ice Age is especially significant, as it implies that the records used by climate scientists date from a time when the Earth was relatively cold, thereby exaggerating the significance of today's temperature rise.

According to the researchers, the evidence confirms suspicions that today's "unprecedented" temperatures are simply the result of examining temperature change over too short a period of time.

The study, about to be published in the journal Energy and Environment, has been welcomed by sceptics of global warming, who say it puts the claims of environmentalists in proper context. Until now, suggestions that the Middle Ages were as warm as the 21st century had been largely anecdotal and were often challenged by believers in man-made global warming.

Dr Philip Stott, the professor emeritus of bio-geography at the University of London, told The Telegraph: "What has been forgotten in all the discussion about global warming is a proper sense of history."

According to Prof Stott, the evidence also undermines doom-laden predictions about the effect of higher global temperatures. "During the Medieval

Warm

Period, the world was warmer even than today, and history shows that it was a wonderful period of plenty for everyone."

In contrast, said Prof Stott, severe famines and economic collapse followed the onset of the Little Ice Age around 1300. He said: "When the temperature started to drop, harvests failed and England's vine industry died. It makes one wonder why there is so much fear of warmth."

The United Nation's Intergovernmental Panel on Climate Change (IPCC), the official voice of global warming research, has conceded the possibility that today's "record-breaking" temperatures may be at least partly caused by the Earth recovering from a relatively cold period in recent history. While the evidence for entirely natural changes in the Earth's temperature continues to grow, its causes still remain mysterious.

Dr Simon Brown, the climate extremes research manager at the Meteorological Office at Bracknell, said that the present consensus among scientists on the IPCC was that the Medieval Warm Period could not be used to judge the significance of existing warming.

Dr Brown said: "The conclusion that 20th century warming is not unusual relies on the assertion that the Medieval Warm Period was a global phenomenon. This is not the conclusion of IPCC."

He added that there were also doubts about the reliability of temperature proxies such as tree rings: "They are not able to capture the recent warming of the last 50 years," he said.

Dear Mr. Matthews,

I have not read the criticism on the website you refer to, but will add to Mike Mann's response in a small, but hopefully helpful, way.

Comparison of the Mann and Jones proxy-based reconstruction with instrumental temperature data *is* a valid comparison to make, provided that the reconstruction is *calibrated* to represent the instrumental record and provided that the *uncertainties* in the calibration are taken into account when making the comparison.

That is, after all, the purpose of calibration - to allow two different data sets to be compared!

As is clear from their article, Mann and Jones do undertake a careful calibration and only make comparisons after the calibration, and their comparison figure includes their estimated uncertainty range. Thus the conclusions they draw (regarding whether recent warming is unprecedented) are valid and are supported by their analysis.

This does not mean that future work, perhaps using new proxy records or different methods for calibration or for estimating calibration uncertainties, will not change those conclusions. But it remains true that their conclusions are supported by their analysis.

As an example of a poor comparison, see the piece by Fred Pearce on page 5 of 12 July 2003 issue of New Scientist. This is a short news article about the Mann and Jones paper, and it unfortunately shows a comparison figure without the associated calibration uncertainties. That is not a good comparison. I mention this in case you were thinking of including a diagram in your article, perhaps showing the Mann and Jones results. If you do, then it will only be valid for comparing the recent instrumental temperatures with the proxy-based reconstruction of earlier temperatures if the reconstruction uncertainties are included. Try to avoid the mistake that Fred Pearce made.

Regards

Tim

Hi Mike,

I agree completely with your analysis. I don't get so many requests as you, but even so get enough to mean that I ignore most - I just pick a few at random to respond to. As Phil is away, I picked this. He's already come back with a second request, which I answered, but that's all he'll get from me. I'll

At 13:56 03/10/2003, you wrote:

Tim,

Many kind thanks for going out of your way to respond to this. Colleagues have increasingly been warning me against "taking the bait" too often (which this seems another attempt at), and so I resisted giving the detailed response that you have nicely provided (as well as I could have myself, I might add). They tried to bog Ben Santer down with distractions, they've been trying to do the same to me, and its supposed to be a warning to the rest of us. So the trick is to find the middle ground between responding to most egregious and potentially damaging accusations, and not swinging at every ball they throw your way. Its thus very helpful if friends and colleagues can take up a bit of the slack now and then, as you have so graciously done...

This guy has written such trash before on the subject, that I assume he's out to do a hatchet job and there is little that we can do to change that. But your response was very helpful. It will be interesting to see what comes of this, thanks once again,

mike

p.s. I never saw the graph in Fred Pearce's piece, since the online version didn't show it. But it does sound problematic from what you describe.

At 9:56 AM 10/3/2003 +0100, Tim Osborn wrote:

Dear Mr. Matthews,

I have not read the criticism on the website you refer to, but will add to Mike Mann's response in a small, but hopefully helpful, way.

Comparison of the Mann and Jones proxy-based reconstruction with instrumental temperature data **is** a valid comparison to make, provided that the reconstruction is **calibrated** to represent the instrumental record and provided that the **uncertainties** in the calibration are taken into account when making the comparison.

That is, after all, the purpose of calibration - to allow two different data sets to be compared!

As is clear from their article, Mann and Jones do undertake a careful calibration and only make comparisons after the calibration, and their comparison figure includes their

estimated uncertainty range. Thus the conclusions they draw (regarding whether recent warming is unprecedented) are valid and are supported by their analysis.

This does not mean that future work, perhaps using new proxy records or different methods for calibration or for estimating calibration uncertainties, will not change those conclusions. But it remains true that their conclusions are supported by their analysis.

As an example of a poor comparison, see the piece by Fred Pearce on page 5 of 12 July 2003 issue of New Scientist. This is a short news article about the Mann and Jones paper, and it unfortunately shows a comparison figure without the associated calibration uncertainties. That is not a good comparison. I mention this in case you were thinking of including a diagram in your article, perhaps showing the Mann and Jones results. If you do, then it will only be valid for comparing the recent instrumental temperatures with the proxy-based reconstruction of earlier temperatures if the reconstruction uncertainties are included. Try to avoid the mistake that Fred Pearce made.

Regards

Tim

At 21:11 02/10/2003, Michael E. Mann wrote:

Dear Mr. Matthews,

Unfortunately Phil Jones is travelling and will probably be unable to offer a separate reply. Since your comments involve work that is his as well, I have therefore taken the liberty of copying your inquiry and this reply to several of his British colleagues.

The comparisons made in our paper are well explained therein, and your statements belie the clearly-stated qualifications in our conclusions with regard to separate analyses of the Northern Hemisphere, Southern Hemisphere, and globe.

An objective reading of our manuscript would readily reveal that the comments you refer to are scurrilous. These comments have not been made by scientists in the peer-reviewed literature, but rather, on a website that, according to published accounts, is run by individuals sponsored by ExxonMobile corporation, hardly an objective source of information.

Owing to pressures on my time, I will not be able to respond to any further inquiries from you. Given your extremely poor past record of reporting on climate change issues, however, I will leave you with some final words. Professional journalists I am used to dealing with do not rely upon un-peer-reviewed claims off internet sites for their sources of information. They rely instead on peer-reviewed scientific research, and mainstream, rather than fringe, scientific opinion.

Sincerely,

Michael E. Mann

At 08:30 PM 10/2/2003 +0100, Robert Matthews wrote:

Dear Professor Mann

I'm putting together a piece on global warming, and I'll be making reference to your paper in Geophysical Research Letters

with Prof Jones on "Global surface temperatures over the past two millennia".

When the paper came out, some critics argued that the paper actually showed that there have been three periods in the last 2000 years which were warmer than today (one just prior to AD 700, one just after, and one just prior to AD 1000). They also claimed that the paper could only conclude that current temperatures were warmer if one compared the proxy data with other data sets. (For an example of these arguments, see:

<<http://www.co2science.org/journal/2003/v6n34c4.htm>><http://www.co2science.org/journal/2003/v6n34c4.htm>)

I'd be very interested to include your rebuttals to these arguments in the piece I'm doing. I must admit to being confused by why proxy data should be compared to instrumental data for the last part of the data-set. Shouldn't the comparison be a consistent one throughout ?

With many thanks for your patience with this

Robert Matthews

Thanks Tom,

In fact, I'm almost done with a brief (<750 word) response that addresses all of these issues, and I'll be looking forward to comments on this. Hope to send it out later today,
mike

At 12:05 PM 10/8/2003 -0600, Tom Wigley wrote:

Folks,
I agree with Kevin that any response should be brief.
On the second page of their comment, SBL quote some of the caveat statements in their earlier papers. The irony is that they do not heed their own caveats. If taken literally, all these proxy data problems would mean that one can draw no conclusions about the existence or otherwise of the MWE or LIA as global phenomena. This is what we say (I hope -- at least I have said this in the paper cited below) - - but our over-bold skeptics say that these anomalous intervals *did* exist. You can't have it both ways -- and basically what BS are doing is a confidence trick. What is still needed here is an analysis of the BS method to show that it could be used to prove anything they wanted. I am still concerned about 'our' dependence on treerings. Are our results really dependent on one region pre 1400 as SNL state? Is the problem of nonclimate obfuscating factors in the 20th century enough to screw up calibrations on moderate to long timescales? If not, we need to state and document this clearly. Does this problem apply to both widths and densities? Are the borehole data largely garbage? I recall a paper of Mike's on this issue that I refereed last year -- and there was something in GRL (I think) very recently pointing out some serious potential problems. Finally, did we really say what SBL claim we did in their p. 1 point (2)? Surely the primary motive for all of this paleo work is that it DOES have a bearing on

human-induced climate effects?

Tom.

Michael E. Mann wrote:

Thanks Kevin,

I agree w/ your take on this. We need to come up with a short, but powerful rebuttal.

According to Judy Jacobs, we're only allowed 750 words, so we will need to be even more

sparing and precise in our words that in the original Eos piece. By the way, we have 3

weeks to submit (i.e., our response is due October 27).

We need to focus on the key new claims, while simply dismissing, by reference to earlier

writings, the recycled ones. The Kalnay et al paper seems to be the new darling of the

contrarians, and your precise wording on this will be very helpful. Phil, Tim and

others should be able to put to rest, in one or two sentences, the myths about urban

heat bias on the CRU record. A few words from Malcolm and Keith on the biological tree

growth effects would help too. The comments on the various paleo figures are confusing

and inconsistent, but from what I can tell, just plain wrong. I'll draft some words on

that.

I'll just continue to assimilate info and suggestions from everyone over the next week

or so, and then try to put this in the form a rough draft rebuttal to send out.

Thanks for your quick reply. Looking forward to hearing back from others,

mike

At 09:16 AM 10/6/2003 -0600, Kevin Trenberth wrote:

Hi Mike et al

Firstly, you should know that comments by myself and the group at NCDC (Vose et al) on

the Kalnay and Cai Nature paper were accepted (after a rebuttal and review process), and

then fine tuned. But it is a slow process and Kalnay and Cai have yet to finalize their

rebuttal. I am attaching FYI the "final" version of my comment. NCDC deals with the

problems with the records.

My reaction to the reply is as follows:

The first page deals with comments on proxy records and their problems. I think we

should agree that there are issues with proxy records, they are not the same as

instrumental records (which have their own problems), but they are all we have.

However, some are better than others (e.g. borehole) and annual or better resolution is

highly desirable in particular to make sure that anomalies are synchronous. The records

are not really the issue here, it is their use (and abuse).

There are several charges about only US or Northern Europe that can be quickly dealt

with. However the main points are on p 2.

We know from the observational record that global or hemispheric means are typically

small residuals of large anomalies of opposite signs so that large warm spots occur

simultaneously with large cold regions (witness last winter).

This fact means that we need high temporal resolution (annual or better) AND an ability

to compute hemispheric averages based on a network. The Soon and Baliunas approach

fails dismally on both of these critical points.

BS point out that Fig 2 of Mann and Jones show some temperatures as high as those in the

20th C. (They are wrong, do they mean Fig 2 of

M03?) You can counter that by looking at China where this is far from true.

I would be inclined to respond with a fairly short minimalist but powerful rebuttal,

focussing mostly on the shortcomings of BS and not defending the M03 and other records.

It should point out (again) that their methodology is fundamentally flawed and their

conclusions are demonstrably wrong. For this, the shorter the better.

Regards

Kevin

Michael E. Mann wrote:

Dear Colleagues,

Sorry to have to bother you all with this-- I know how busy our schedules are, and this

comes at an unfortunately busy time for many of us I would guess. But I think we *do*

have to respond, and I'm hoping that the response can be, again, something we all sign

our names to.

I've asked Ellen for further guidance on the length limits of our response, and the due

date for our response. The criticisms are remarkably weak, and easy to reply to in my

view. S&B have thus unwittingly, in my view, provided us with a further opportunity to

expose the most egregious of the myths perpetuated by the contrarians (S&B have managed

to cram them all in there) in the format of a response to their comment.

Their comment includes a statement about how the article is all based on Mann et al [1999] which is pretty silly given what is stated in the article, and what is shown in Figure 1. It would be appropriate to begin our response by pointing out this obvious straw man.

Then there is some nonsense about the satellite record and urban heat islands that Phil, Kevin, and Tom W might in particular want to speak to. And Malcolm and Keith might like to speak to the comments on the supposed problems due to non-biological tree growth effects (which even if they were correctly described, which they aren't, have little relevance to several of the reconstructions shown, and all of the model simulation results shown). There is one paragraph about Mann and Jones [2003] which is right from the Idsos' "Co2 science" website, and Phil and I and Tim Osborn and others have already spoken too. I will draft a short comment on that.

I'd like to solicit individual comments, sentences or paragraphs, etc. from each of you on the various points raised, and begin to assimilate this into a "response". I'll let you know as soon as I learn from Ellen how much space we have to work with.

Sorry for the annoyance. I look forward to any contributions you can each provide towards a collective response.

Thanks,
mike

Dear Dr. Mann (and co-authors of the Forum piece that appeared in EOS),

Dr. Willie Soon and his co-authors have submitted a reply to your Forum piece that I

have accepted. Let me outline below the official AGU procedure for replies so that you

know the options available. I have sent these same instructions to Dr. Soon.

As you wrote the original piece you now have the opportunity to see their comment

(attached) on your Forum piece. You may decide whether or not to send a reply. If you

choose not to reply - their reply will be published alone.

Should you decide to reply then your response will be published along with their comment

on your paper. One little twist is that if you submit a reply, they are allowed to see

the reply, but they can't comment on it. They have two options: they can let both

their and your comments go forward and be published together or (after viewing your

reply) they also have the option of withdrawing their comment. In the latter case, then

neither their comment or your reply to the comment will be published. Yes this is a

little contorted, but these are the instructions that I received from Judy Jacobs at

AGU.

I have attached the pdf of their comment. Please let me know within the next week

whether you and your colleagues plan to prepare a reply. If so, then you would have

several weeks to do this.

I have copied Lee Zirkel and Judy Jacobs of AGU as this paper is out of the ordinary and

I want to be sure that I am handling all this correctly.

I look forward to hearing from you regarding your decision on a reply.

Best regards,

Ellen Mosley-Thompson

HI Tom,

My understanding of the papers from the borehole community ever since the 1997 GRL article by Huang et al is that they no longer believe that the data has proper sensitivity to variations prior to about AD 1500--in fact, I don't believe anyone in that community now feels they can meaningfully go farther back than that. Huang contributed the section on boreholes in chapter 2 for IPCC (2001), and wrote the very words to that effect... Now, the possible influences on boreholes might lead to inferred trends in GST that are different from those in SAT is a different one. A number of independent recently published papers by (Beltrami et al; Stiglitz et al; Mann and Schmidt) and others have demonstrated that there should be expectations for significant differences between past SAT (what we care about) and GST variations (what boreholes in the best case scenario see) due to snowcover influences, etc. We don't have time to discuss that in this very short piece, so I tried, as briefly as possible, to cover our bases on this issue, in a way that doesn't really stir up the pot w/ the borehole folks... I'm interested in any further thoughts on the above, mike
At 12:38 PM 10/9/03 -0400, Tom Crowley wrote:

Hi, I don't understand why we cannot cite the borehole data for the MWP - that in a sense is the only legitimate data set that shows a ~1 C cooling from the MWP to the LIA - forget the deforestation problem for the moment, that is later in time - if the borehole data for the MWP are legitimate then there is still a case for concluding that the MWP was significantly warmer than the LIA
tom

Thanks Phil,
a few brief responses and inquiries below...
cheers,

mike

At 04:17 PM 10/9/03 +0100, Phil Jones wrote:

Mike,

Away Oct 11-16, so here are a few comments. A few times the tone could be a little less

antagonistic. We don't want to inflame things any further. So remove the word laundry.

fair enough. You *should* have seen the first draft I wrote. This is quite toned down now...

1. With the boreholes do we want to get one of the borehole group to sign up, eg Henry Pollack?

Would add a lot of weight to the last 500 year argument.

this has merit. unfortunately though I think it might open up a hornets nest of the author list is not identical to the original list of authors on the Eos article. Other thoughts on this...

2. On the UHI, there was a paper in a very recent issue of J. Climate by Tom Peterson, arguing

for the USA that this is non-existent. Issue with UHI is one of large versus local scale. One

station doesn't influence large-scale averages. All studies which look at the UHI

comprehensively find very little effect (an order of magnitude smaller than the warming). Also the warming

in the 20th century is very similar between the NH and SH and between the land and

ocean components.

let me see if I can fit one or two sentences in on this and keep the article under the length.

Also, if we can't estimate temperature histories accurately, then SB can't say it

was

warmer in their MWP period. They believe the 20th century instrumental data when they

want to.

yes, one of a large number of amazing contradictions in their reasoning...

3. Keith is away till next week. I doubt we will have the space to do the 'tree issues' justice.

Best just to say that there are an (equal) number of non tree-based proxy series??

I do think we need to address their spurious description of the putative biological effects. Any way that you can get in touch w/ Keith for a response, perhaps just to this one point? Also, Malcolm might want to comment on the current wording?

4. Ray, Malcolm and Henry Diaz have a Science Perspectives piece coming out in the next couple of weeks on the MWP/E. This is also relevant.

good!

5. Don't think we will get away with the last paragraph. Whether we want it is an issue ??

Shouldn't we be sticking to the science.

ok, I wasn't sure myself--yet it is a powerful rebuke, and reminds people that the objection to the validity of their work goes beyond just our article--and that's important. Does someone want to try to rephrase this paragraph, maybe reducing it to a couple sentences?

Cheers
Phil

At 21:37 08/10/2003 -0400, Michael E. Mann wrote:

Dear co-authors,
Attached is a draft response, incorporating suggestions Kevin, Tom W, and Michael. I've aimed to be as brief as possible, but hard to go much lower than 750 words and still address all the key issues. 750 words, by the way, is our allotted limit.

Looking forward to any comments. Feel free to send an edited version if you prefer, and

I'll try to assimilate all of the suggested edits and suggestions into a single revised draft. If you can get comments to me within the next couple days, that would be very

helpful as we're working on a late October deadline for the final version.

Thanks for your continued help,
mike

At 20:02 09/10/2003, Michael E. Mann wrote:

Dear All,
I like all of Kevin's changes. Please work with his version as a template for any additional suggested changes. I'll incorporate the additional comments received from Phil and Tom W and others afterwards...
thanks,
mike

Dear Mike and co-authors,
I've now had a chance to go through the drafts and comments etc. Working from Kevin's version, here are some suggestions to consider:
(1) Are you sure that what we saw is the final version of S03, after any EOS editing, etc.? Wouldn't want any of the S03 quotes used here to get changed if they had to edit to reduce the length of their piece!
(2) Suggested re-ordering of the end of point (1): 'it holds in some cases for tree-ring density measurements at higher latitudes, but rarely for annual ring widths.'
(3) Suggested re-wording near start of point (2): '"clearly shows temperatures in the MWP that are as high as those in the 20th century" is misleading because it is true for only the early 20th century. The hemispheric warmth of the late 20th century is anomalous in a long-term context.' (with underlining of either 'late' or 'is' for emphasis). Of course, this suggestion needs to be checked carefully (e.g., is it only the 'early' 20th century that is exceeded by some earlier temperatures?). But it is an important change because it is not actually 'false' or 'untrue' if some part of the 20th century was exceeded earlier - they don't specify which part, so their statement is (probably deliberately) vague rather than wrong. The above suggestion simply points this out.
(4) Related to this comment, is the question of whether the actual reconstruction (not

instrumental observations) in the late 20th century exceeds all reconstructed values (central estimates) prior to the 20th century. My copy of Mann and Jones (2003) has poor quality figures, so this is hard for me to tell. It appears that it might be true, but only right at the end - i.e. the 1980 value of the filtered series. If it is really only at the end, and a 40-year smoothing filter is used, then I would be concerned about this statement appearing in the response if it depends upon applying the filter right up to the end of the record. Doing so requires some assumption about values past the end of the series. This in itself is problematic, but especially so if the assumption were that the trend was extrapolated to produce values for input to the filter. Of course, if the straight 40-year mean from 1941-1980 of the reconstruction exceeds all other 40-year means of the reconstruction, then I'd be happy with the statement.

(5) I don't like point (3) on the boreholes. It relies on the "optimal" borehole series of Mann et al. (2003), a result that I have some concerns about and which is being used here to imply less uncertainty than really exists over this issue. In the EOS paper we included this and the "non-optimal" gridded borehole series, so we were leaving open some uncertainty. I'm not saying that I prefer/believe the Huang et al. series either, since I agree that extracting the temperature signal from the borehole data is very difficult. I just don't like to imply it has been solved when it hasn't.

(6) Can we provide a supporting reference for the statement in point (4) about land use changes leading to an overall cooling?

(7) I like the final paragraph as it is, possibly dropping the last "We feel it is time to move on" line.

Cheers
Tim

From: Jan Esper <esper@wsl.ch>
Subject: minor explosion
Cc: Wilson Rob <rjwilson_dendro@blueyonder.co.uk>

Hi Keith

thank you for the message and the comments to the Siberia draft. We are intending to finalize a draft when Rob is coming over and we go on a sampling trip to the Bavarian Forest and E-Germany. We will then also discuss of data-overlap issue again and might include some extra figure with our record re-calculated (without Tornetraesk and Polar Ural).

However, I (Jan) am not sure that we should have another figure with only the Mann and the (reduced) Esper series. Second, it seems that Mann used the density records from these two sites only (not ring width). Lets see.

We would really like to send you the final draft, and ask you to become the fourth author? We ask this not only because of the "minor explosion" that might happen, but also because some of the arguments in the draft were made earlier by you anyway. What do you think?

Take care

Jan and Dave

CC

R Wilson

Jan

with respect to the overlap problem we could agree to differ for now -I think the problem is much more in the earlier period anyway but I suggest you go ahead and submit it anyway. There are some minor wording points but nothing that affects the meaning. You know that in my opinion the recent similarity in the records is driven by instrumental data inclusion (or calibration against instrumental data) and that Mann's earlier data are strongly biased towards summer and northern land signals. I think you will start a minor explosion - but that is what science needs .

I looked at your tree-line data and thought them very interesting. In my opinion the way you directed the interpretation was what drew your criticisms . For a climate journal you should have been pointing out the complicated regional responses (to the temperature record) rather than trying to state a simple overall response. The data are clearly important and you should have no trouble publishing them if you rethink the approach to

the description (no work needed). I think Boreas or Arctic and Alpine Res. are better targets though. I enjoyed the discussions also and it is frustrating not to be able to get up to speed with your other projects. I will get back to you when I have looked more at the idea of the big review paper.

the very best to you and all

Keith

At 09:55 AM 10/8/03 +0200, Jan Esper wrote:

Hi Keith

with respect to our EOS draft, I am still thinking about the data overlap argument you made.

1. I still believe that the overlap is not that significant, and that the significance is changing dramatically with time (less in more recent centuries).
2. With respect to the aim of the paper, we do NOT intend to explain the similarity between the records. We rather address that the recons differ in the lower frequency domains AND are much more similar in the higher frequency domains. I believe that this is crucial. (One could also say that we only address the dissimilarity, and the arguments related to that.)

I appreciated the discussions we had very, very much (especially the one in the night before the official meeting).

Take care

Jan

Mike and all

Hi , just back from a trip and only now catching up with important emails. Given

the restricted time and space available to furnish a response to SB comments ,

I offer the following mix of comment and specific wording changes:

I agree that the S+B response is designed to deflect criticism by confusing the issues

rather than answering our points.

In fact they fail to address any of the 3 specific

issues we raised Namely , 1. the need for critical evaluation of proxy inputs , 2. the

need for a consistent assimilation of widespread (dated and well resolved) records,

3. the essential requirement for objective/quantitative calibration (scaling) of the input

records to allow for assessment of the uncertainties when making comparisons of different reconstructions and when comparing early with recent

temperatures.

Their own , ill-conceived and largely subjective approach did not take

account of the uncertainties and problems in the use of palaeodata that they chose to

highlight in their opening remarks.

I would be in favour of stating something to this effect at the outset of our response.

Also , as regards the tree-ring bit , I fully concur with the sense of your text as

regards Section 1, but suggest the following wording (to replace ",rarely for annual

ring widths, and almost entirely at higher latitudes.")

"but in certain high-latitude regions only. Where this is the case , these relatively

recent

(ie post 1950) data are not used in calibrating temperature reconstructions. In many other

(even high-latitude) areas density or ring-width records display no bias."

In the spirit of healthy debate - I agree with Tim's remarks , warning against presenting a

too

sanguine impression that the borehole debate is closed (though I do think it is closing!).

I also believe , as you already know, that the use of a recent padding algorithm to extend smoothed data to the present time, is inappropriate if it assumes the continuation of a recent trend. This is likely to confuse , rather than inform, the wider public about the current climate state .
Finally , I repeat my earlier remarks (made before EOS piece published) that we are missing an opportunity to say that a warm Medieval period per se is not a refutation of anthropogenic warming , {as its absence is no proof}, if we do not understand the role of specific forcings (natural and anthropogenic) that influenced medieval and current climates.
Cheers

Keith

thanks Caspar,
I agree--its important to emphasize this point, and I'm glad you
recognized that we were
underplaying it...
mike
At 10:25 AM 10/14/2003 -0600, Caspar Ammann wrote:

Mike,
looks good to me. It is one of these points where they can persuade
journalists that
they are 'correct' and it actually got into newspapers and finally
to the senate floor
this way. The more we are able to explain why the first half of the
20th century warmed
up naturally, the more confidence we get on the detection of the
anthropogenic signal
afterwards.
Caspar
Michael E. Mann wrote:

Dear All,
In response to Caspar's suggestion, which I agree with, I propose
rephrasing item "2"
as follows:
2) The statement by S03 that the Mann and Jones [2003]
reconstruction "clearly shows
temperatures in the MWP that are as high as those in the 20th
century" is misleading if
not false. M03 emphasize that it is the late, and not the early or
mid 20th century
warmth, that is outside the range of past variability. Mann and
Jones emphasize
conclusions for the Northern Hemisphere, noting that those for the
Southern Hemisphere
(and globe) are indeterminate due to a paucity of southern
hemisphere data. Consistent
with M03, they conclude that, late 20th century Northern Hemisphere
mean temperatures
are anomalous in a long-term (nearly two millennium) context.
Any comments?
Thanks,
mike

Subject: Re: draft
Hi Mike,

it now looks good to me indeed including the new last paragraph following Tom's wording.

The only point I would highlight a little more is in point 2): Maybe it could be stated

that the early part of the 20th century is within the natural range whereas the late

20th century, the main point of the AGU position statement and also in M03, is clearly

outside. Please also add a second 'n' in my name...

Cheers, and thanks for your momentum on this,

Caspar

Michael E. Mann wrote:

Dear All,

I agree with each of Tom W's suggestions. Adopting them, by the way, brings us down to

738 words.

So pending any revised language from Keith/Malcolm in response to Michael O's comment on

paragraph 2, I'm putting out a last call for comments, sign-ons, etc...

Thanks,

mike

At 08:00 AM 10/14/2003 -0600, Tom Wigley wrote:

Some minor points

para. 2 -- should it be 'an' ensuing rather than 'the' ensuing?

para. 2 -- I still think 'each' (line 3) is unnecessary

para. 4 -- no comma after '(and globe)'

re boreholes, does the point about comparing late 20th century with a 'much longer

period' 1000 years ago help us? Given that the 1000 years ago data is highly lowpass

filtered, if one *did* have a series with a temporal resolution that allowed a

legitimate comparison, then the likelihood of a warmer interval 1000 years ago must be

higher.

In any event, the time scale issue will not be meaningful to most readers. The key point

is the data reliability/uncertainty. I would just say something like

...

".... taken into account. For times more than 500 years ago, uncertainties in the borehole reconstructions preclude any useful quantitative comparison."

Finally, I would like the last para. retained, but I suggest shorter wording as ...

".... as indicating that SB03 misinterpreted and misrepresented the paleoclimatological literature. The controversy".

My problem here is twofold. First, they really say nothing directly about 'mainstream

scientific opinion' (except that they clearly disagree with it). At issue is not the

mainstream opinion, but their interpretation of the literature and their illogical

conclusions. Second, they may have misrepresented the results of their work, but we do

not address this issue so it comes here as a non sequitur. In fact, just what such

'misrepresentation' consists of, and why it might be judged as 'misrepresentation' is a

subtle issue. Hence my revision -- which retains the word 'misrepresentation', but in a

different context.

Tom.

Michael E. Mann wrote:

Thanks Tim and Malcolm,

The latest round of suggestions were extremely helpful. I've accepted them w/ a few

minor tweaks (attached). We're at 765 words--I think AGU will let us get away w/ that...

So, comments from others?

Thanks,

mike

At 02:11 PM 10/14/2003 +0100, Tim Osborn wrote:

S03 argue that borehole data provide a conflicting view of past temperature histories.

To the contrary, the borehole estimates for recent centuries shown in M03 may be

consistent with other estimates, provided consideration is given to statistical

uncertainties, spatial sampling and possible influences on the ground surface [e.g.,

snow cover changes--Beltrami and Kellman, 2003]. It is not meaningful to compare the

late 20th century with a much longer period 1000 years ago [Bradley et al., 2003],

especially given the acknowledged limitations [Pollack et al., 1998] of borehole data.

At 05:05 PM 10/14/2003 -0400, Michael E. Mann wrote:

Dear All,
To those I thought might be interested, I've provided an example for discussion of smoothing conventions. Its based on a simple matlab script which I've written (and attached) that uses any one of 3 possible boundary constraints [minimum norm, minimum slope, and minimum roughness] on the 'late' end of a time series (it uses the default 'minimum norm' constraint on the 'early' end of the series).
Warning: you needs some matlab toolboxes for this to run...
The routines uses a simple butterworth lowpass filter, and applies the 3 lowest order constraints in the following way:
1) minimum norm: sets mean equal to zero beyond the available data (often the default constraint in smoothing routines)
2) minimum slope: reflects the data in x (but not y) after the last available data point. This tends to impose a local minimum or maximum at the edge of the data.
3) minimum roughness: reflects the data in both x and y (the latter w.r.t. to the y

value of the last available data point) after the last available data point. This tends to impose a point of inflection at the edge of the data---this is most likely to preserve a trend late in the series and is mathematically similar, though not identical, to the more ad hoc approach of padding the series with a continuation of the trend over the past 1/2 filter width. The routine returns the mean square error of the smooth with respect to the raw data. It is reasonable to argue that the minimum mse solution is the preferable one. In the particular example I have chosen (attached), a 40 year lowpass filtering of the CRU NH annual mean series 1856-2003, the preference is indicated for the "minimum roughness" solution as indicated in the plot (though the minimum slope solution is a close 2nd)... By the way, you may notice that the smooth is effected beyond a single filter width of the boundary. That's because of spectral leakage, which is unavoidable (though minimized by e.g. multiple-taper methods). I'm hoping this provides some food for thought/discussion, esp. for purposes of IPCC...

views on climate
Michael and Tom --
I'm forwarding for your entertainment an exchange that followed from
my being quoted in
the Harvard Crimson to the effect that you and your colleagues are
right and my
"Harvard" colleagues Soon and Baliunas are wrong about what the
evidence shows
concerning surface temperatures over the past millennium. The
cover note to faculty
and postdocs in a regular Wednesday breakfast discussion group on
environmental science
and public policy in Harvard's Department of Earth and Planetary
Sciences is more or
less self-explanatory.
Best regards,
John

Colleagues--

I append here an e-mail correspondence I have engaged in over the past few days trying

to educate a Soon/Baliunas supporter who originally wrote to me asking how I could think

that Soon and Baliunas are wrong and Mann et al. are right (a view attributed to me,

correctly, in the Harvard Crimson). This individual apparently runs a web site on which

he had been touting the Soon/Baliunas position.

While it is sometimes a mistake to get into these exchanges (because one's interlocutor

turns out to be ineducable and/or just looking for a quote to reproduce out of context

in an attempt to embarrass you), there was something about this guy's formulations that

made me think, at each round, that it might be worth responding.

In the end, a couple

of colleagues with whom I have shared this exchange already have suggested that its

content would be of interest to others, and so I am sending it to our "environmental

science and policy breakfast" list for your entertainment and, possibly, future

breakfast discussion.

The items in the correspondence are arranged below in chronological order, so that it

can be read straight through, top to bottom.

Best,

John

To: Nick Schulz
Subject: Harvard Crimson coverage of Soon / Baliunas controversy
Dear Nick Schultz --

I am sorry for the long delay in this response to your note of September 12. I have been swamped with other commitments.

As you no doubt have anticipated, I do not put Mann et al. in the same category with Soon and Baliunas.

If you seriously want to know "Why not?", here are three ways one might arrive at what I regard as the right conclusion:

(1) For those with the background and patience to penetrate the scientific arguments, the conclusion that Mann et al. are right and Soon and Baliunas are wrong follows from reading carefully the relevant Soon / Baliunas paper and the Mann et al. response to it:

W. Soon and S. Baliunas, "Proxy climatic and environmental changes of the past 1000 years", *Climate Research*, vol. 23, pp 89ff, 2003.

M. Mann, C. Amman, R. Bradley, K. Briffa, P. Jones, T. Osborn, T. Crowley, M. Hughes, M.

Oppenheimer, J. Overpeck, S. Rutherford, K. Trenberth, and T. Wigley, "On past temperatures and anomalous late-20th century warmth", *EOS*, vol 84, no. 27, pp 256ff, 8 July 2003.

This is the approach I took. Soon and Baliunas are demolished in this comparison.

(2) Those lacking the background and/or patience to penetrate the two papers, and seriously wanting to know who is more likely to be right, have the option of asking somebody who does possess these characteristics -- preferably somebody outside the handful of ideologically committed and/or oil-industry-linked professional climate-change skeptics -- to evaluate the controversy for them.

Better yet, one could poll a number of such people. They can easily be found by checking the web pages of earth sciences, atmospheric sciences, and environmental sciences departments at any number of major universities.

(3) The least satisfactory approach, for those not qualified for (1) and lacking the time or initiative for (2), would be to learn what one can about the qualifications

(including publications records) and reputations, in the field in question, of the authors on the two sides. Doing this would reveal that Soon and Baliunas are, essentially, amateurs in the interpretation of historical and paleoclimatological records of climate change, while the Mann et al. authors include several of the most published and most distinguished people in the world in this field. Such an investigation would also reveal that Dr. Baliunas' reputation in this field suffered considerable damage a few years back, when she put her name on an incompetent critique of mainstream climate science that was never published anywhere respectable but was circulated by the tens of thousands, in a format mimicking that of a reprint from the Proceedings of the National Academy of Sciences, in pursuit of signatures on a petition claiming that the mainstream findings were wrong. Of course, the third approach is the least satisfactory because it can be dangerous to assume that the more distinguished people are always right. Occasionally, it turns out that the opposite is true. That is one of several good reasons that it pays to try to penetrate the arguments, if one can, or to poll others who have tried to do so. But in cases where one is not able or willing to do either of these things -- and where one is able to discover that the imbalance of experience and reputation on the two sides of the issue is as lopsided as here -- one ought at least to recognize that the odds strongly favor the proposition that the more experienced and reputable people are right. If one were a policy maker, to bet the public welfare on the long odds of the opposite being true would be foolhardy.

Sincerely,
John Holdren

PS: I have provided this response to your query as a personal communication, not as fodder for selective excerpting on your web site or elsewhere. If you do decide that you would like to propagate my views on this matter more widely, I ask that you convey my response in its entirety.

At 11:16 AM 10/13/2003 -0400, you wrote:

I have the patience but, by your definition certainly, not the background, so I suppose

it is not surprising I came to a different conclusion. I guess my problem concerns what lawyers call the burden of proof. The burden weighs heavily much more heavily, given the claims on Mann et.al. than it does on Soon/Baliunas. Would you agree?

Falsifiability for the claims of Mann et. al. requires but a few examples, does it not? Soon/Baliunas make claims that have no such burden. Isn't that correct?

Best,
Nick

From: John P. Holdren [[3]mailto:john_holdren@harvard.edu]
Sent: Tuesday, October 14, 2003 5:54 PM
To: Nick Schulz
Subject: RE: Harvard Crimson coverage of Soon / Baliunas controversy
Nick--

Yes, I can see how it might seem that, in principle, those who are arguing for a strong

and sweeping proposition (such as that "the current period is the warmest in the last

1000 years") must meet a heavy burden of proof, and that, because even one convincing

counter-example shoots the proposition down, the burden that must be borne by the

critics is somehow lighter. But, in practice, burden of proof is an evolving thing --

it evolves as the amount of evidence relevant to a particular proposition grows.

To choose an extreme example, consider the first and second laws of thermodynamics.

Both of these are "empirical" laws. Our confidence in them is based entirely on

observation; neither one can be "proven" from more fundamental laws. Both are very

sweeping. The first law says that energy is conserved in all physical processes. The

second law says that entropy increases in all physical processes. So, is the burden of

proof heavier on somebody who asserts that these laws are correct, or on somebody who

claims to have found an exception to one or both of them? Clearly, in this case, the

burden is heavier on somebody who asserts an exception. This is in part because the

two laws have survived every such challenge in the past. No exception to either has

ever been documented. Every alleged exception has turned out to be traceable to a

mistake of some kind. This burden on those claiming to have found an exception is so

strong that the US Patent Office takes the position, which has been upheld in court,

that any patent application for an invention that violates either law can be rejected

summarily, without any further analysis of the details.

Of course, I am not asserting that the claim we are now in the warmest period in a

millennium is in the same league with the laws of thermodynamics. I used the latter

only to illustrate the key point that where the burden is heaviest depends on the state

of prior evidence and analysis on the point in question -- not simply on whether a

proposition is sweeping or narrow.

In the case actually at hand, Mann et al. are careful in the nature of their claim.

They write along the lines of "A number of reconstructions of large-scale temperature

changes support the conclusion" that the current period is the warmest in the last

millennium. And they write that the claims of Baliunas et al. are "inconsistent with

the preponderance of scientific evidence". They are not saying that no shred of

evidence to the contrary has ever been produced, but rather that analysis of the

available evidence as a whole tends to support their conclusion.

This is often the case in science. That is, there are often "outlier" data points or

apparent contradictions that are not yet adequately explained, but still are not given

much weight by most of the scientists working on a particular issue if a strong

preponderance of evidence points the other way. This is because the scientists judge it

to be more probable that the outlier data point or apparent contradiction will

ultimately turn out to be explainable as a mistake, or otherwise explainable in a way

that is consistent with the preponderance of evidence, than that it will turn out that

the preponderance of evidence is wrong or is being misinterpreted. Indeed, apparent

contradictions with a preponderance of evidence are FAR more often due to measurement

error or analysis error than to real contradiction with what the preponderance

indicates.

A key point, then, is that somebody with a PhD claiming to have identified a

counterexample does not establish that those offering a general proposition have failed

in their burden of proof. The counterexample itself must pass muster as both valid in

itself and sufficient, in the generality of its implications, to invalidate the

proposition.

In the case at hand, it is not even a matter of an "outlier" point or other seeming

contradiction that has not yet been explained. Mann et al. have explained in detail why

the supposed contrary evidence offered by Baliunas et al. does NOT constitute a

counterexample. To those with some knowledge and experience in studies of this kind,

the refutation by Mann et al is completely convincing.

Sincerely,

John Holdren

At 08:08 AM 10/15/2003 -0400, you wrote:

Dr. Holdren:

Thank you for your thoughtful reply. I genuinely appreciate you taking the time.

You are quite right about the laws of thermodynamics. And you are quite right that Mann

et al is not in the same league as those laws and that s not to take anything from their

basic research.

You write to those with knowledge and experience in studies of this kind, the refutation

by Mann et all is completely convincing. Since I do not have what you would consider

the requisite knowledge or experience, I can t speak to that. I ve read the Mann papers

and the Baliunas Soon paper and the Mann rebuttal and find Mann s claims based on his

research extravagant and beyond what he can legitimately claim to know. That said, I m

willing to believe it is because I don t have the tools necessary to understand.

But if you will indulge a lay person with some knowledge of the matter, perhaps you

could clear up a thing or two.

Part of the confusion over Mann et al it seems to me has to do not with the research

itself but with the extravagance of the claims they make based on their research.

And yet you write: Mann et al. are careful in the nature of their claim. They write

along the lines of A number of reconstructions of large-scale temperature changes

support the conclusion that the current period is the warmest in the last millennium.

And they write that the claims of Baliunas et al. are inconsistent with the

preponderance of scientific evidence .

That makes it seem as if Mann s not claiming anything particularly extraordinary based

on his research.

But Mann claimed in the NYTimes in 1998 that in their Nature study from that year Our conclusion was that the warming of the past few decades appears to be closely tied to emission of greenhouse gases by humans and not any of the natural factors." Does that seem to be careful in the nature of a claim? Respected scientists like Tom Quigley responded at the time by saying "I think there's a limit to how far you can ever go." As for using proxy data to detect a man-made greenhouse effect, he said, "I don't think we're ever going to get to the point where we're going to be totally convincing." These are two scientists who would agree on the preponderance of evidence and yet they make different claims about what that preponderance means. There are lots of respected climatologists who would say Mann has insufficient scientific basis to make that claim. Would you agree? The Soon Baliunas research is relevant to that element of the debate what the preponderance of evidence enables us to claim within reason. To that end, I don't think claims of Soon Baliunas are inconsistent with the preponderance of scientific evidence. I'll close by saying I'm willing to admit that, as someone lacking a PhD, I could be punching above my weight. But I will ask you a different but related question How much hope is there for reaching reasonable public policy decisions that affect the lives of millions if the science upon which those decisions must be made is said to be by definition beyond the reach of those people? All best,
Nick

To: "Nick Schulz" <nschulz@techcentralstation.com>

From: "John P. Holdren" <john_holdren@harvard.edu>

Subject: RE: Harvard Crimson coverage of Soon / Baliunas controversy
Nick--

You ask good questions. I believe the thoughtfulness of your questions and the progress

I believe we are making in this interchange contain the seeds of the answer to your

final question, which, if I may paraphrase just a bit, is whether there's any hope of

reaching reasonable public-policy decisions when the details of the science germane to

those decisions are impenetrable to most citizens.

This is a hard problem. Certainly the difficulty is not restricted to climate science and policy, but applies also to nuclear-weapon science and policy, nuclear-energy science and policy, genetic science and policy, and much more. But I don't think the difficulties are insurmountable. That's why I'm in the business I'm in, which is teaching about and working on the intersection of science and technology with policy.

Most citizens cannot penetrate the details of what is known about the how the climate works (and, of course, what is known even by the most knowledgeable climate scientists about this is not everything one would like to know, and is subject to modification by new data, new insights, new forms of analysis). Neither would most citizens be able to understand how a hydrogen bomb works (even if the details were not secret), or what factors will determine the leak rates of radioactive nuclides from radioactive-waste repositories, or what stem-cell research does and promises to be able to do.

But, as Amory Lovins once said in addressing the question of whether the public deserved and could play a meaningful role in debates about nuclear-weapon policy, even though most citizens would never understand the details of how nuclear weapons work or are made, "You don't have to be a chicken to know what to do with an egg." In other words, for many (but not all) policy purposes, the details that are impenetrable do not matter.

There CAN be aspects of the details that do matter for public policy, of course. In those cases, it is the function and the responsibility of scientists who work across the science-and-policy boundary to communicate the policy implications of these details in ways that citizens and policy makers can understand. And I believe it is the function and responsibility of citizens and policy makers to develop, with the help of scientists and technologists, a sufficient appreciation of how to reach judgments about plausibility and credibility of communications about the science and technology relevant to policy choices so that the citizens and policy makers are NOT disenfranchised in policy decisions where science and technology are germane.

How this is best to be done is a more complicated subject than I am prepared to try to

explicate fully here. (Alas, I have already spent more time on this interchange than I could really afford from other current commitments.) Suffice it to say, for now, that improving the situation involves increasing at least somewhat, over time, the scientific literacy of our citizens, including especially in relation to how science works, how to distinguish an extravagant from a reasonable claim, how to think about probabilities of who is wrong and who is right in a given scientific dispute (including the question of burden of proof as you and I have been discussing it here), how consulting and polling experts can illuminate issues even for those who don't understand everything that the experts say, and why bodies like the National Academy of Sciences and the Intergovernmental Panel on Climate Change deserve more credibility on the question of where mainstream scientific opinion lies than the National Petroleum Council, the Sierra Club, or the editorial page of the Wall Street Journal. Regarding extravagant claims, you continue to argue that Mann et al. have been guilty of this, but the formulation of theirs that you offer as evidence is not evidence of this at all. You quote them from the NYT in 1998, referring to a study Mann and co-authors published in that year, as saying

"Our conclusion was that the warming of the past few decades appears to be closely tied to emission of greenhouse gases by humans and not any of the natural factors."

and you ask "Does that seem to be careful in the nature of a claim?" My answer is:

Yes, absolutely, their formulation is careful and appropriate.

Please note that they

did NOT say "Global warming is closely tied to emission of greenhouse gases by humans

and not any of the natural factors." They said that THEIR

CONCLUSION (from a

particular, specified study, published in NATURE) was that the warming of THE PAST FEW

DECADES (that is, a particular, specified part of the historical record) APPEARS (from

the evidence adduced in the specified study) to be closely tied...

This is a carefully

specified, multiply bounded statement, which accurately reflects what they looked at and

what they found. And it is appropriately contingent --"APPEARS to be closely tied" --

allowing for the possibility that further analysis or new data could later lead to a

different perspective on what appears to be true.

With respect, it does not require a PhD in science to notice the appropriate boundedness

and contingency in the Mann et al. formulation. It only requires an open mind, a

careful reading, and a degree of understanding of the character of scientific claims and

the wording appropriate to convey them that is accessible to any thoughtful citizen.

That is why I'm an optimist.

You go on to quote the respected scientist "Tom Quigley" as holding a contrary view to

that expressed by Mann. But please note that: (1) I don't know of any Tom Quigley

working in this field, so I suspect you mean to refer to the prominent climatologist Tom

Wigley; (2) the statements you attribute to "Quigley" do not directly contradict the

careful statement of Mann (that is, it is entirely consistent for Mann to say that his

study found that recent warming appears to be tied to human emissions and for Wigley to

say that that there are limits to how far one can go with this sort of analysis, without

either one being wrong); and (3) Tom Wigley is one of the CO-AUTHORS of the resounding

Mann et al. refutation of Soon and Baliunas (see attached PDF file).

I hope you have found my responses to be of some value. I now must get on with other

things.

Best,

John Holdren

From: Tim Osborn <t.osborn@uea.ac.uk>
To: evelyn.smith@noaa.gov, "Christopher D Miller" <Christopher.D.Miller@noaa.gov>
Subject: Fwd: confidential assessment of GC04-203
Date: Fri Oct 24 10:20:33 2003

Dear Evelyn and Chris,
re. proposal review GC04-203, Meko et al. "A synthesis of 19th century climate data for the United States from paleo, archival and instrumental sources".

I have read the "Reviewer conflict of interest and confidentiality..." document and can state that I have no conflict of interest and will abide by the confidentiality provisions etc.

I reviewed a very similar proposal by this group 1 year ago, and enclose my review of that proposal below. The new proposal has taken into account my two main concerns from last time, which were:

- (i) that creation only of a blended data set that contained a time varying mixture of proxy and instrumental data would limit the usefulness because its quality would be time varying, perhaps in an unquantified way, and independent study of errors between proxy and observed data would be prevented; and
- (ii) that the proposed work was not very innovative in terms of the applications for which the new information would be used.

Both of these points have been addressed adequately and so I now rate it "Excellent (5)" for scientific/technical merit, and "High (5)" for importance/relevance and applicability. One issue that I would like to raise, however, is that the need for quantifying uncertainty/error in the reconstructions/database is not given much coverage in the proposal. It is mentioned, but not focused on. For many applications (testing models, comparison with other reconstructions, detection of unusual climate trends/events), explicitly quantified error estimates are essential. These often change magnitude through time, and thus should be estimated in such a way as to allow this. They may also change with time scale (often being lower for, e.g., a decadal mean than for a single year's value), and again the error estimation method should capture this. I do not think that this issue detracts from the quality of the proposal. Instead I am mentioning it in the hope that this comment can be passed on to the proposers, in the event that the project is funded, so that they can be prompted into placing the appropriate emphasis on quantifying uncertainty.

Apologies for being late yet again, and best regards,
Tim

<christopher.d.miller@noaa.gov>

Dear Irma and Chris,

Re. proposal review GC03-512, PI: David Meko "A 19th century data catalog"

First of all, I confirm that there is no conflict of interest etc.

Now to my review...

(1) Scientific Merit

Rating: Good

Comments:

I completely agree with the rationale behind improving data sets of 19th century climate (see my comments below on "Relevance to climate change programme"), and the proposers have identified the most relevant data sources available for the US. The objectives and workplan are generally reasonable, but I have rated it "good" rather than "very good" or "excellent" because it does not seem as scientifically innovative or challenging as it might. Some particular concerns are highlighted below. I am very wary about the proposed approach of integrating the data sources together to produce a single climate product. Obviously the data sources have to be used in combination, for calibration of proxy data or for assessment of possibly dubious early instrumental data, *but* combining them all into a single product only will be very restrictive for future use, assessment, improvements. Much better would be to produce instrumental-only series for whatever length is available, and tree-ring only series for the full length (i.e., into the late 19th and 20th centuries, despite the availability of instrumental data for these periods). Blending them into a single analysis is of some, but limited, use and comparisons of different periods and with (e.g.) model simulations can only ever be done by taking into account error bars that vary dramatically in time and are only estimates of the "true" errors - and the error estimates may be underestimates if based only on residuals or covariances during the 20th century.

No mention is made of using the 19th century data to consider key issues such as difference between tree-ring and ground borehole temperatures (they differ more in the 19th century, in terms of trend, than in other centuries), possibly taking into account land-use change. No mention is made of using the 19th century data to assess multi-century temperature reconstructions and why they differ. These are issues of great importance. No mention is investigating seasonal dependence of temperature changes, which are greater in existing temperature products during the 19th century than in the 20th century and which has important implications for the calibration of proxy (including tree-ring) data against summer or annual data and the need to more clearly define the true seasonal response of proxy data.

Despite these concerns, the proposed work is certainly worthy of funding and

the extra items of interest that I mention above could be achieved using the data generated here, in some future project.

(2) Relevance to climate change programme

Rating: High

Comments:

The 19th century is certainly of particular importance, not just for the reasons outlined in the proposal but also because this century shows some of the biggest disagreements in warming trend between various quasi-hemispheric temperature reconstructions and between proxy and instrumental data and between different seasons of instrumental data. Additional data sources are definitely required, and additional digitisation, homogenisation and intercomparison of data sets is necessary. For these reasons, work such as that proposed here is essential for helping to refine answers to questions such as how unusual is late twentieth century climate and detection of climate change signals against the noise of natural climate variability.

Best regards

Tim

Dear All,

This has been passed along to me by someone whose identity will remain
in confidence.

Who knows what trickery has been pulled or selective use of data
made. Its clear that

"Energy and Environment" is being run by the baddies--only a skill
for industry would have

republished the original Soon and Baliunas paper as submitted to
"Climate Research" without

even editing it. Now apparently they're at it again...

My suggested response is:

1) to dismiss this as stunt, appearing in a so-called "journal" which
is already known to

have defied standard practices of peer-review. It is clear, for
example, that nobody we

know has been asked to "review" this so-called paper

2) to point out the claim is nonsense since the same basic result has
been obtained by

numerous other researchers, using different data, elementary
compositing techniques, etc.

Who knows what sleight of hand the authors of this thing have pulled.
Of course, the usual

suspects are going to try to peddle this crap. The important thing is
to deny that this has

any intellectual credibility whatsoever and, if contacted by any
media, to dismiss this for

the stunt that it is..

Thanks for your help,

mike

two people have a forthcoming 'Energy & Environment' paper that's
being unveiled tomoro

(monday) that -- in the words of one Cato / Marshall/ CEI type --
"will claim that Mann

arbitrarily ignored paleo data within his own record and substituted
other data for

missing values that dramatically affected his results.

When his exact analysis is rerun with all the data and with
no data

substitutions, two very large warming spikes will appear that are greater than the 20th century.

Personally, I'd offer that this was known by most people who understand Mann's

methodology: it can be quite sensitive to the input data in the early centuries.

Anyway, there's going to be a lot of noise on this one, and knowing Mann's very thin

skin I am afraid he will react strongly, unless he has learned (as I hope he has) from

the past...."

Dear Thomas, Fortunat, Reto:

You might have wanted to check w/ us first, but thanks anyway for responding to this. We've uncovered the error in what they did. They didn't use the proxy data available on our public ftp site, which I had pointed them too--instead they used a spreadsheet file that my associate Scott Rutherford had prepared. In this file, most of the early series were overprinted at later years. This resulted in the reconstruction becoming increasingly spurious as one goes further back in time--the estimates prior to 1700 or so were rendered meaningless. There were also some other methodological errors that will be detailed shortly, but this was the big one. So they will probably have to retract the paper. You can find out more about this here, on journalist David Appell's "blog": [1]<http://www.davidappell.com/> We also have an op-ed piece going out this afternoon, further detailing the problems. Will send that as soon as its available. I've attached a few other relevant documents, and I'm forwarding another email I sent out to colleagues yesterday, just after I had discovered the main problem in what they've done...

Guys, can you take a look at this.
I think that everything I say here is true! But we've got to be sure.
There are more technical things they did wrong that I want to add, but this is the critical bit--what do you think. Comments? Thanks...
mike

The recent paper by McIntyre and McKittrick (Energy and Environment, 14, 751-771) claims to be an "audit" of the analysis of Mann, Bradley and Hughes (1998) or "MBH98". An audit involves a careful examination, using the same data and following the exact procedures used in the report or study being audited. McIntyre and McKittrick ("MM") have done no such thing, having used neither the data nor the procedures of MBH98. Their analysis is notable only in how deeply they have misrepresented the data, methods, and results of MBH98. Journals that receive critical comments on a previously published papers always provide the authors who are being criticized an opportunity to review the study prior to publication, and offer them the chance to respond. This is standard operating procedure in any legitimate peer-reviewed scientific journal. Mann and colleagues were never given this opportunity, nor were any other leading paleoclimate scientists that we're familiar with. It is unfortunate that the profound errors, and false and misleading statements, and entirely spurious results provided in the McIntyre and McKittrick article were ever allowed to see the light of day by those would have been able to detect them. We suspect the extremely checkered history of "Energy and Environment" has some role to play in this. The authors should retract their article immediately, and issue a public apology to the climate research community for the injustice they have done in publishing and promoting this deeply deceptive and flawed analysis.

Not only were critical errors made in their analysis that render it thoroughly invalid, but

there appear to have been several strikingly subjective decisions made to remove key indicators of the original MBH98 network prior to AD 1600, with a dramatic impact on the resulting reconstruction. It is precisely the over which the numerous indicators were removed (pre 1600 period) during which MM reconstruct anomalous warmth that is in sharp opposition to the cold conditions observed in MBH98 and nearly all other independent published estimates that we know of.

While the authors dutifully cite the small inconsistency between the number of proxy indicators reported by, and found in the public data archive, of Mann et al back in time (there indeed appear to have been some minor typos in the MBH98 paper), it is odd that they do not cite the number of indicators in their putative version of the Mann et al network based on the independent collection of data, back time. The reader is literally left to do a huge amount of detective work, based on the tables in their pages 20-23, to determine just what data have been eliminated from the original Mann et al network. It seems odd, indeed, that their "substitutions" of other versions (or in some case, only apparent, and not actual, versions) of proxy data series for those in the original Mann et al (1998) network has the selective effect of deleting key proxy indicators that contribute dramatic cooling during the 16th century, when the MM reconstruction shows an anomalous warming departure from the Mann et al (1998) and all other published Northern Hemisphere temperature reconstructions.

Here are some blatant examples:

1) The authors (see their Figure 4) substitute a younger version of one of the Jacoby et al Northern Treeline series for the older version used by MBH98. This substitution has effect of removing a predictor of 15th century cooling [Incidentally, MM make much of the tendency for some tree ring series, such as this one, to show an apparent cooling over the past couple decades. Scientists with expertise in dendroclimatology know that this behavior represents a decrease in the sensitivity to temperature in recent decades that likely is related to conditions other than temperature which are limiting tree growth]

2) The authors eliminate, without any justification, the entire dataset of 70 Western North American (WNA) tree-ring series available between 1400 and 1600 (this dataset is represented, by MBH98, in terms of a smaller number of representative Principal Component time series). The leading pattern of variance in this data set exhibits conditions from 1400-1800 that are dramatically colder than the mid and late 20th century, and a very prominent cooling in the 15th century in particular. The authors eliminated this entire dataset because they claimed that the underlying data was not available in the public domain.

In point of fact, not only were the individual WNA data all available on the public ftp site provided by Mann and colleagues: [1]ftp://holocene.evsc.virginia.edu/pub/MBH98/TREE/ITRDB/NOAMER/, but they were also available, despite the claims to the contrary by MM, on NOAA's website as well:

[2]ftp://ftp.ngdc.noaa.gov/paleo/treering/chronologies/northamerica/usa

The deletion of this critical (see Mann et al, 1999) dataset appears to one of the more important censorings performed by MM that allows them to achieve their spurious result of apparent 15th-16th century warmth.

We have not, as yet, finished determining just how many important indicators were subtly censored from the MBH98 dataset by the various subjective substitutions described on pages 20-23. However, given the relatively small number of indicators available between 1400-1500 in the MBH98 network (22-24) and their elimination of some of the more critical ones, it would appear that this subjective censoring of data, alone, explains the spurious, misleading, and deceptive result achieved by the authors.

Incidentally, MBH98 go to great depths to perform careful cross-validation experiments as a function of increasing sparseness of the candidate predictors back in time, to demonstrate statistically significant reconstructive skill even for their earlier (1400-1450) reconstruction interval. MM describe no cross-validation experiments. We wonder what the

verification resolved variance is for their reconstruction based on their 1400-1450 available network, during the independent latter 19th century period?

There are numerous other serious problems that would render the MM analysis completely invalid, even in the absence of the serious issue raised above, and these are detailed below

.

Tim, Phil, Keef:

I suggest a way out of this mess. Because of the complexity of the arguments involved, to an unformed observer it all might be viewed as just scientific nit-picking by "for" and "against" global warming proponents. However, if an "independent group" such as you guys at CRU could make a statement as to whether the M&M effort is truly an "audit", and if they did it right, I think that would go a long way to defusing the issue.

It's clear from the figure that Reno Knuti sent yesterday that something pretty whacky happened in their analysis prior to ~AD1600, and this led Mike to figure out the problem. See:
file:///c:/eudora/attach/nh_temp_rec.jpg

If you are willing, a quick and forceful statement from The Distinguished CRU Boys would help quash further arguments, although here, at least, it is already quite out of control.....yesterday in the US Senate the debate opened on the McCain-Lieberman bill to control CO2 emissions from power plants. Sen Inhofe stood up & showed the M & M figure and stated that Mann et al--& the IPCC assessment --was now disproven and so there was no reason to control CO2 emissions....I wonder how many times a "scientific" paper gets reported on in the Senate 3 days after it is published....

Hi Keith,
sorry--yes, I think the Nature idea would be great. Definitely give it a try!
thanks,
mike

At 06:53 PM 10/30/2003 +0000, Keith Briffa wrote:

Things obviously moving over there - this result looks good. Just thought I'd send this first bit (up to dotted line) of edited version, to illustrate possible toning down?
Have to go now and feed daughter. Will wait til see your joint version first thing tomorrow - rest assured, that am entirely with you on this and still appalled by the MM stuff - but keeping your distance and calm stance is still urged.
all the best to all
any objections if I talk to Nature tomorrow?

Keith

At 01:31 PM 10/30/03 -0500, Michael E. Mann wrote:

Guys,

So the verification RE for the "censored" NH mean reconstruction? -6.64
The verification RE for the original MBH98 NH mean reconstruction: 0.42
I think the case is really strong now!

What if were to eliminate the discussion of all the other technical details (and just say they exist), and state more nicely that these series were effectively censored by their substitutions, and that by removing those series which they censored, I get a similar result, with a dismal RE.

And most people would keep the RE of 0.42 over the RE of -6, right? So this would make that point. I think we also need to say something about the process, etc. (the intro was based on something that Malcolm/Ray had originally crafted).

Thoughts, comments? Thanks,

mike

I'm thinking of a note saying basically this, and attaching this figure.

Could everybody sign on to something like this?

Thanks for all your help,

mike

At 05:11 PM 10/30/2003 +0000, Keith Briffa wrote:

Ray et al

I agree with this idea in principle. Whatever scientific differences and fascination with the nuances of techniques we may /may not share, this whole process represents the most despicable example of slander and down right deliberate perversion of the scientific process, and bias (unverified) work being used to influence public perception and due political process. It is, however, essential that you (we) do not get caught up in the frenzy that these people are trying to generate, and that will more than likely lead to error on our part or some premature remarks that we might regret. I do think the statement re Mike's results needs making, but only after it can be based on repeated work and in full collaboration of us all. I am happy to push Tim to take the lead and collaborate in this - and I feel we could get sanction very quickly from the DEFRA if needed. BUT this must be done calmly, and in the meantime a restrained statement but out saying we have full confidence in Mike's objectivity and independence - which we can not say of the sceptics. In fact I am moved tomorrow to contact Nature and urge them to do an editorial on this. The political machinations in Washington should NOT dictate the agenda or scheduling of the work - but some cool statement can be made saying we believe the "prats have really fucked up someway" - and that the premature publication of their paper is reprehensible. Much of the detail in Mikes

response though is not sensible (sorry Mike) and is rising to their bate.

Keith

Thanks very much Tim,
I was hoping that the revisions would ally concerns people had.
I'll look forward to your comments on this latest draft. I agree w/ Malcolm on the need to be careful w/ the wording in the first paragraph. The first paragraph is a bit of relic of a much earlier draft, and maybe we need to rethink it a bit. Takinig the high road is probably very important here. If *others* want to say that their actions represent scientific fraud, intellectual dishonesty, etc. (as I think we all suspect they do), lets let *them* make these charges for us!
Lets let our supporters in higher places use our scientific response to push the broader case against MM. So I look forward to peoples attempts to revise the first par. particular. I took the liberty of forwarding the previous draft to a handfull of our closet colleagues, just so they would have a sense of approximately what we'll be releasing later today--i.e., a heads up as to how MM achieved their result...
look forward to us finalizing something a bit later--I still think we need to get this out ASAP...
mike
SAAt 03:01 AM 10/31/2003 +0000, f055 wrote:

Dear all,
I've just finished preparing a detailed response offline, only to log on to send it to you all and find new versions from Mike plus more comments and information. Well, I don't have time to change my message now, so will paste it below this message. But bear in mind that the new draft may well have allayed many of my concerns - in particular, a quick glance shows the figure to be much more convincing than the one Mike circulated earlier, indeed it seems to be utterly convincing! I'll reply again on Friday morning once I've had time to read the new draft. In the meantime, here is my message as promised.

Dear MBH (cc to CRU),
The number of emails has been rather overwhelming on this issue and I'm struggling to catch up with them! But I will attempt to catch up with a few things here...
(1) The single worst thing about the whole M&M saga is not that they did their study, not that they did things wrong (deliberately or by accident), but that neither they nor the journal took the necessary step of investigating whether the difference between their results and yours could be explained simply by some error or set of errors in their use of the data or in their implementation of your method. If it turns out, as looks likely from Mike's investigation of this, that their results are erroneous, then they and the journal will have wasted countless person-hours of time and caused much damage in the climate policy arena.
(2) Given that this is the single worst thing about the saga, we must not go and do exactly the same in rushing out a response to their paper. If some claims in the response turned out to be wrong, based on assumptions about what M&M did or assumptions about how M&M's assumptions affect the result, then it would end up with a number of iterations of claim

and counter claim. Ultimately the issue might be settled, but by then the waters could be so muddied that it didn't matter.

(3) Not only do I advise against an overly rushed response, but I'm also wondering whether it really ought to be only from MBH, for three reasons.

(i) It is your paper/results that are being attacked.

(ii) It is difficult to endorse everything that Mike has put in the draft response because I don't know 100% of the details of MBH and the MBH data. Sure, I can endorse some things, but others I wouldn't know. Sure, I accept Mike's explanation because he's looked at this stuff for 4 days and I believe he'll have got it right - but that's different to an independent check. That must come from Ray or Malcolm if possible.

(iii) If it does come to any independent assessment of who's right and who's wrong, then it would be difficult for us to be involved if we had already signed up to what some might claim to be a knee-jerk reaction to the M&M paper. If that happened, then you would want us to be free to get involved to make sure the process was fair and informed.

This sounds like a cop out, but - like I say - I'm not sure about point (3) so feel free to try to convince me otherwise if you wish. Anyway Keith or Phil may be happy to sign up to a (quick or slow) response, despite my reservations above.

I really advise a very careful reading of M&M and their supplementary website to ensure that everything in the response is clearly correct - precisely to avoid point (2). I've only just started to do this, but already have some questions about the response that Mike has drafted.

(a) Mike, you say that many of the trees were eliminated in the data they used. Have you concluded this because they entered "NA" for "Not available" in their appendix table? If so, then are you sure that "NA" means they did not use any data, rather than simply that they didn't replace your data with an alternative (and hence in fact continued to use what Scott had supplied to them)? Or perhaps "NA" means they couldn't find the PC time series published (of course!), but in fact could find the raw tree-ring chronologies and did their own PCA of those? How would they know which raw chronologies to use? Or did you come to your conclusion by downloading their "corrected and updated" data matrix and comparing it with yours - I've not had time to do that, but even if I had and I

found some differences, I wouldn't know which was right seeing as I've not done any PCA of western US trees myself? My guess would be that they downloaded raw tree-ring chronologies (possibly the same ones you used) but then applied PCA only to the period when they all had full data - hence the lack of PCs in the early period (which you got round by doing PCA on the subset that had earlier data). But this is only a guess, and this is the type of thing that should be checked with them - surely they would respond if asked? - to avoid my point (2) above. And if my guess were right, then your wording of "eliminated this entire data set" would come in for criticism, even though in practise it might as well have been.

(b) The mention of ftp sites and excel files is contradicted by their email record on their website, which shows no mention of excel files (they say an ASCII file was sent) and also no record that they knew the ftp address. This doesn't matter really, since the reason for them using a corrupted data file is not relevant - the relevant thing is that it was corrupt and had you been involved in reviewing the paper then it could have been found prior to publication. But they will use the email record if the ftp sites and excel files are mentioned.

(c) Not sure if you talk about peer-review in the latest version, but note that

they acknowledge input from reviewers and Fred Singer's email says he refereed it - so any statement implying it wasn't reviewed will be met with an easy response from them.

(d) Your quick-look reconstruction excluding many of the tree-ring data, and the verification RE you obtain, is interesting - but again, don't rush into

using these in any response. The time series of PC1 you sent is certainly different from your standard one - but on the other hand I'd hardly say you "get a similar result" to them, the time series look very different (see their fig 6d). So the dismal RE applies only to your calculation, not to their reconstruction. It may turn out that their verification RE is also very negative, but again we cannot assume this in case we're wrong and they easily counter the criticism.

(e) Claims of their motives for selective censoring or changing of data, or for the study as a whole, may well be true but are hard to prove. They would claim that their's is an honest attempt at reproducing a key scientific result. If they made errors in what they did, then maybe they're just completely out of their depth on this, rather than making deliberate errors for the purposes of achieving preferred results.

(f) The recent tree-ring decline they refer to seems related to tree-ring-width not density. Regardless of width of density, this issue cannot simply be dismissed as a solved problem. Since they don't make much of an issue out of it, best just to ignore it.

(g) [I'm rambling now into an un-ordered list of things, so I'll stop soon!] The various other problems relating to temperature data sets, detrended standard deviations, PCs of tree-ring subsets etc. sound likely errors - though I've got no way of providing the independent check that you asked for. But it is again a bit of a leap of faith to say that these *explain* the different results that they get. Certainly they throw doubt on the validity of

their results, but without actually doing the same as them it's not possible to say if they would have replicated your results if they hadn't made these errors. After all, could the infilling of missing values have made much difference to the results obtained, something that they made a good deal of fuss about?

(h) To say they "used neither the data nor the procedures of MBH98" will also be an easy target for them, since they did use the data that was sent to them and seemed to have used approximately the method too (with some errors that you've identified). This reproduced your results to some extent (certainly not perfectly, but see Fig 6b and 6c). Then they went further to redo it with the "corrected and updated" data - but only after first

doing approximately what they claimed they did (i.e. the audit).

These comments relate to random versions of the draft response, so apologies if they don't all seem relevant to the current draft. I don't have these in front of me, here at home, so I'm doing this from memory of what I've read over the past few days. But nevertheless, the point is that a quick response would ultimately require making a number of assumptions about what they did and assumptions about whether this explains the differences or not - assumptions that might be later shot down (in part only, at most, but still sufficient to muddy the debate for most outsiders).

A quick response ought to be limited to something like:

The recent paper by McIntyre and McKittrick (2003; hereafter MM03) claims to be an "audit" of the analysis of Mann, Bradley and Hughes (1998; hereafter MBH98). MM03 are unable to reproduce the Northern

Hemisphere temperature reconstruction of MBH98 when attempting to use the same proxy data and methods as MBH98, though they obtain something similar with clearly anomalous recent warming (their Figure 6c). They then make many modifications to the proxy data set and repeat their analysis, and obtain a rather different result to MBH98.

Unfortunately neither M&M nor the journal in which it was published took the necessary step of investigating whether the difference between their results and MBH98 could be explained simply by some error or set of errors in their use of the data or in their implementation of the MBH98 method. This should have been an essential step to take in a case such as this where the difference in results is so large and important. Simple errors must first be ruled out prior to publication. Even if the authors had not undertaken this by presenting their results to the authors of MBH98, the journal should certainly have included them as referees of the manuscript.

A preliminary investigation into the proxy data and implementation of the method has already identified a number of likely errors, which may turn out to be the cause of the different results. Rather than repeating M&M's failure to follow good scientific practise, we are withholding further comments until we can - by collaboration with M&M if possible - be certain of exactly what changes to data and method were made by M&M, whether these changes can really explain the differences in the results, and eventually which (if any) of these changes can be justified as equally valid (given the various uncertainties that exist) and which are simply errors that invalidate their results.

Hope you find this all helpful, and despite my seemingly critical approach, take them in the spirit with which they are aimed - which is to obtain a strong and hard hitting rebuttal of bad science, but a rebuttal that cannot be buried by any minor inaccuracies or difficult-to-prove claims.

Best regards

Tim

Keith and Phil,

you will have seen Stephen McIntyre's request to us. We need to talk about it, though my initial feeling is that we should turn it down (with carefully worded/explained reason) as another interrim stage and prefer to make our input at the peer-review stage.

In the meantime, here is an email (copied below) to Mike Mann from McIntyre, requesting data and programs (and making other criticisms). I do wish Mike had not rushed around sending out preliminary and incorrect early responses - the waters are really muddied now. He would have done better to have taken things slowly and worked out a final response before publicising this stuff. Excel files, other files being created early or now deleted is really confusing things!

Anyway, because McIntyre has now asked Mann directly for his data and programs, his request that *we* send McIntyre's request to Mann has been dropped (I would have said "no" anyway).

So it's just the second bit, that we review part 2 of this response, that needs to be answered.

Cheers

Tim

Dear All:

The excuses seem to be becoming desperate. Unjustified assertion that I fail to understand

"Myles' comments and/or work on trying the detect/attribute climate change" does not stop

the attribution study being an error. The problem is that I do understand what is being

done, and I am willing to say why it is GIGO.

Tim Allen said;
In a message dated 19/11/03 08:47:16 GMT Standard Time,
m.allen1@physics.ox.ac.uk writes:

I would just like
to add that those of us working on climate change detection and
attribution
are careful to mask model simulations in the same way that the
observations
have been sampled, so these well-known dependencies of nominal
trends on the
trend-estimation technique have no bearing on formal detection and
attribution results as quoted, for example, in the IPCC TAR.

I rejected this saying:
At 09:31 21/11/2003, RichardSCourtney@aol.com wrote:
>It cannot be known that the 'masking' does not generate additional
>spurious trends. Anyway, why assume the errors in the data sets are
>geographical and not?. The masking is a 'fix' applied to the model
>simulations to adjust them to fit the surface data known to contain
>spurious trends. This is simple GIGO.
Now, Tim Osborn says of my comment;
In a message dated 21/11/03 10:04:56 GMT Standard Time,
t.osborn@uea.ac.uk writes:

Richard's statement makes it clear, to me at least, that he
misunderstands
Myles' comments and/or work on trying the detect/attribute climate
change.
As far as I understand it, the masking is applied to the model to
remove
those locations/times when there are no observations. This is quite
different to removing those locations which do not match, in some
way, with
the observations - that would clearly be the wrong thing to do. To
mask
those that have no observations, however, is clearly the right thing
to do
- what is the point of attempting to detect a simulated signal of
climate
change over some part of (e.g.) the Southern Ocean if there are no
observations there in which to detect the expected signal? That
would
clearly be pointless.

Yes it would. And I fully understand Myles' comments. Indeed, my
comments clearly and
unarguably relate to Myles comments. But, as my response states,
Myles' comments do not
alter the fact that the masked data and the unmasked data contain
demonstrated false
trends. And the masking may introduce other spurious trends. So, the
conducted

attribution study is pointless because it is GIGO. Ad hominem insults don't change that.

And nor does the use of peer review to block my publication of the facts of these matters.

Richard

Subject: Towards a Sustainable Energy Economy deadline
Date: Wed, 7 Jan 2004 10:35:14 -0000

Dear All,
Is any one involved in proposals for this initiative?

Please let me know.
Janice

First call for research proposals
A call for expressions of interest for participation in Consortia, Research
Groups, Networks, Collaborative Proposals and Capacity Building
Closing date: 5pm, Monday 19 January 2004

Intending applicants should note that all those receiving funding from this
programme will be expected to collaborate with the UK Energy Research Centre
following its establishment on 1st April 2004.

Introduction

The Towards a Sustainable Energy Economy programme (TSEC) is aimed at
enabling the UK to access a secure, safe, diverse and reliable energy supply
at competitive prices, while meeting the challenge of global warming. The
Engineering and Physical Science Research Council (EPSRC), Economic and
Social Research Council (ESRC) and Natural Environment Research Council
(NERC) jointly have funding of £28 million for the programme, which is
co-ordinated by NERC on behalf of the three Research Councils, with
participation from the Biotechnology and Biological Sciences Research
Council (BBSRC) and Council for the Central Laboratory of the Research
Councils (CCLRC). The Councils are advised on the use of the programme's
funds by the TSEC Scientific Advisory Committee.

TSEC is an interdisciplinary research programme that will adopt whole
systems integrated approaches. The Research Councils' working definition of
'a whole systems approach' is: "A whole systems integrated methodology
demanding a truly interdisciplinary approach that facilitates the joint
working of engineering, technological, natural, environmental, social and
economic scientists to tackle fundamental issues (such as sustainable
energy)." A whole systems approach should ensure that new work carried out
complements current and planned activities of the individual Research
Councils in the area concerned and will take into account known

understanding for the issues addressed.

The TSEC programme will provide a focus for, but will not be the only source of, energy research in the UK. As such, the TSEC programme will aim to make an impact on UK energy research by promoting this whole systems approach. Proposers wishing to carry out research under TSEC should familiarise themselves with the role of TSEC in the energy research landscape, as described in Annex 1.

What research will TSEC support?

Up to £12 million of the programme's funding will be used to establish the UK Energy Research Centre (UKERC) by 1st April 2004, for which the Councils have already invited full proposals. The Centre's two major activities will be its own research programme and the co-ordination of a National Energy Research Network.

The remainder of the TSEC programme's funds (at least £16 million) will be used to support research that will operate independently of, but complementary to, the research done by UKERC. Calls for proposals will be broadly under the following themes:

- .
carbon management

- .
nuclear power

- .
renewable energy

- .
managing new uncertainties.

In keeping with the whole systems approach of the programme, applications are invited from all disciplines that have a research interest in any of the themes (eg the environmental, social, economic and technological aspects of nuclear power).

What areas are covered in this call?

This first call covers all aspects of the TSEC programme but the Research

Councils wish to focus initially on two of the themes: nuclear power and managing new uncertainties. It is anticipated that a further call focused in particular on the other two themes - carbon management and renewable energy - will be issued in mid-2004.

The present call invites expressions of interest for participation in:

- Consortia under the theme Nuclear Power - Keeping the nuclear option open

- Research Groups under the theme Managing new uncertainties - The socio-economic challenges and implications of moving towards a sustainable energy economy

- Expressions of interest for Networks and Collaborative proposals will also be considered, under either of the themes Carbon management and Renewable energy.

- Expressions of Interest for preparation for projects (Capacity Building) will also be considered under any of the areas except Nuclear power.

The key features of Consortia, Research Groups, Networks, Collaborative Proposals and Capacity Building are described in the Application Process.

Consortium bids: Nuclear power - Keeping the Nuclear Option Open
The research challenges in fission R&D span areas as diverse as maintaining and extending the life of existing generation plant; management of the current and future fission waste legacy; technology for future fission power generation; and research that can contribute to an open and informed debate on the current and future role for nuclear power in the UK's energy supply industry. The scope of this theme has been broken down into three main topics:

- maintaining current generation capacity

fission within a sustainable energy economy

·
future fission power.

The sponsors intend to commission one or more large, integrated, multidisciplinary projects that can address the research challenges, with the scope of projects potentially cutting across the three topics.

Further details on the scope of the theme and consortia requirements can be found in Annex 2.

Research Group bids: Managing new uncertainties - The Socio-Economic Challenges and Implications of Moving Towards a Sustainable Energy Economy

The aim of this theme is to facilitate research on the cross-cutting socio-economic challenges and implications of moving towards a sustainable energy economy and their interactions with broader technological, engineering, and environmental issues. It offers opportunities for productive, interdisciplinary research within and beyond the socio-economic field, with the potential to contribute to the development of whole-systems approaches to energy issues. Many of the potential research issues have resonance in a number of other areas of public policy and are not specific to energy. In line with the aims of the programme, this theme is not constrained by traditional disciplinary or Research Council boundaries, whilst focusing on the socio-economic research agenda. Although a number of the proposed topics and questions focus on UK and European issues, many are generic and could be applied to both OECD and developing country contexts.

Possible topics identified under this theme include:

·
Processes of long-run change in socio-technical systems

·
Vulnerability, resilience and adaptiveness

·
Services, systems of provision and consumption practices

·
Policies in natural monopolies and liberalised markets

Public attitudes and processes of governance

Energy in the global context

Integrated appraisal of energy systems.

This framework should be regarded as illustrative, not definitive. Researchers are encouraged to define and justify alternative topics and questions which would contribute towards the TSEC programme's overall objectives.

More detail on this theme can be found in Annex 3.

Expressions of Interest under the themes Carbon management and Renewable energy will be considered in this call. However, the following brief indication of the scope of these two themes is given for initial guidance only; a detailed scope will be provided in the next call, expected to be mid 2004.

Carbon management

Conventional energy research is often vertically divided, so that research looks at the use of individual fuels, or energy use in particular industrial, commercial or domestic sectors. There needs to be more "cross-boundary" and "whole systems" research, looking at how different technologies and social/environmental factors might be optimised to deliver the overall objectives. The following are two examples of the type of issues which should be addressed.

Fuel switching and renewables

Displacing coal and petroleum with natural gas and/or biogas, or biofuels, or renewables are alternative ways of reducing carbon dioxide (CO₂) emissions. These options require a full whole lifecycle approach to carbon management, integrating environmental, engineering, resource, economic and social dimensions. Issues such as length and type of supply chains, emissions associated with agriculture, fuel processing, infrastructure and construction need to be fully understood to limit the risk that emissions are increased or displaced to another part of the energy/resource chain.

Carbon dioxide capture and storage

The continued use of fossil fuels will demand effective carbon management, particularly through reduction of the associated CO₂ emissions. The greatest long-term potential for reduced CO₂ emissions to the atmosphere from fossil fuels is likely to be through capturing CO₂ from large industrial point sources before it enters the atmosphere, and then sequestering it back into the bio/geosphere by geological means. The research challenges include: the mechanisms of large-scale carbon capture at source, CO₂ storage, transport and distribution, and geological sequestration, monitoring and verification technologies as well as modelling the long term fate of CO₂ injected into a variety of geological scenarios. Understanding is also needed of the potential risk posed by CO₂ leakage into terrestrial and marine settings, and of the economic risks, costs and benefits, public acceptability and regulatory issues associated with moving towards large-scale CO₂ capture.

Renewable energy

The objectives for TSEC in this area will centre on work that supports the development of renewable and sustainable energy systems of relevance to the UK economy. Specifically, it will: encourage the introduction of renewable and sustainable energy systems into the UK economy; encourage consideration of renewable energy in the context of social/economic/environmental issues and carbon management; and provide data for the development of policy. TSEC will fund research that is complementary to that supported through other Research Council activities, such as the ongoing Sustainable Power Generation and Supply Programme (SUPERGEN). Again, the following is purely an example of the type of research which could be funded.

Carbon cycle audits

Audits of full lifecycle carbon (or carbon equivalents of other greenhouse gases emitted in the lifecycle) need to be undertaken, and the energy balances of different renewable energy generating technologies need to be considered and understood, if true impacts on carbon reduction are to be achieved. For example, if energy crops are to be encouraged, then consequences on land use change, aquifer recharge, and rainfall run off need to be fully understood. It would also be important to ensure that the crops are 'low-input' in terms of energy usage and that the energy balance is therefore positive. Environmental impacts of growing energy crops would have to be compared with the alternative land use (food crops, set-aside, etc)), and consideration given to their potential economic and social impacts.

Risks, barriers and incentives in renewables innovation

Innovation will be essential in the renewables industry if the sector is to

play a central role in future energy supply. Research is required to understand and quantify the risks inherent in the development of new technology and the barriers preventing its exploitation to inform both the priorities of future renewable energy R&D and the development of future market instruments and incentives that can encourage the effective management of risk and enable the exploitation of the outputs of R&D. In the longer term, new disruptive technology may significantly affect the operation of the energy market, and research is required to investigate how incentives and market instruments can adapt to changing market conditions while still providing a long term framework within which companies can make capital investments requiring a return on capital over long (20-30 year) timescales. (In addition to research on such issues relating specifically to renewables there are opportunities for broader cross-cutting research on these issues under the Managing New Uncertainties Theme).

The Application Process

The schemes and theme areas under which EoIs will be accepted in this call are highlighted in colour in the table below.

Nuclear power
Managing new uncertainties
Carbon management
Renewable energy
Consortia
Research groups
Networks
Collaborative proposals
Capacity building

Characteristics of the schemes

Consortium

A Consortium will comprise a number of academic groups, normally from different disciplines and institutions, working in partnership with appropriate stakeholders and users to design and deliver a collaborative programme of world-class research. It is expected that the consortium will deliver higher quality research outputs than groups working in isolation. This call for expressions of interest is open to all potential partners of a research consortium, irrespective of their existing links to academic research in the field. Consortia may be funded at a value of up to £5m. Expressions of interest can be submitted by individuals, existing groups, and existing or new collaborations. However, where expressions of interest are made by a group or collaboration, the Research Councils reserve the right to take forward those expressions in total or in part during the Consortium-building process, potentially excluding elements of proposed

collaborations.

Research Groups

A Research Group will be a national focal point for research where researchers can collaborate on long-term inter-disciplinary projects. It will facilitate the building of strong relationships with research users, international collaboration and the development of the careers of new and outstanding researchers.

Funded initially for five years, Research Groups will be expected to provide the training for postgraduate students and other new researchers where appropriate, and to improve opportunities for securing co-funding or sponsorship from sources outside the Science Vote. Applications for Research Group funding will normally be expected to be in the range of £200k - £600k per annum although applications outside this range can be considered.

Networks

A major task of UKERC will be to co-ordinate a National Energy Research Network that will draw in all significant research activities. However, once the components of this network are known, the TSEC programme will wish to support new research 'nodes' that complement them. Such complementary activities would normally be UK-based networks that link research groups and industrial organisations, across disciplines, to develop new or enhanced collaborations.

Collaborative Proposals

These will be intended to support focussed, co-ordinated, collaborative research into specific issues and will be expected to enhance opportunities for inter-disciplinary collaboration. A minimum of three eligible institutions are required for a proposal under this scheme, each of which will be separately awarded funds. The consortium will retain ownership and management of the science programme, and a lead institution will be expected to act as co-ordinator.

Collaboration awards will provide funding for up to five years with costs ranging, as required by the research, from modest sums up to approximately £2M. Proposals may include tied research studentships.

Proposers are free to submit expressions of interest for one or more themes.

Capacity building

For projects that require considerable preparation, applicants may submit an Expression of Interest for capacity building, to a maximum of £50k, for:

support for a researcher to work in a different science department for a period of up to 12 months (eg for a natural scientist to work in a social science department);

support for an overseas researcher to work in a UK institution, or for a UK researcher to work in an overseas institution, for up to 12 months focusing on interdisciplinary research issues;

support for a series of four or more interdisciplinary events (involving social and natural scientists) over a 12 month period;

scoping studies, focusing on any of the TSEC themes. Applicants must demonstrate the interdisciplinary nature of the proposed research. Awards may be up to 12 months in duration

Eligibility

Standard Research Council eligibility criteria will apply to this call; those normally eligible to participate in any Research Council programme can apply. Research Council funding can only be awarded to UK universities, Research Council institutes, Government Research Establishments and not-for-profit research organisations. Organisations and industry which are themselves ineligible for receipt of Research Council funding may participate, using their own cash or in-kind support.

Applications from members of the public or individuals outside academia will not be accepted.

Academic expressions of interest may be submitted by leaders of individual research groups within one or more universities. While existing groups of researchers are able to apply as a team, it should be recognised that the Research Councils may recommend the building of new partnerships involving only a minority of members from existing collaborations. Where there is scope to do so, it is recommended that individuals submit their own expression of interest on behalf of their group.

The Selection Process

An initial sift of EoIs will be conducted by expert panels established by the Programme Scientific Advisory Committee or by the SAC. Applications will be judged on their quality, innovation, originality and compliance with the objectives of the programme.

Quality - The proposal should indicate clear potential to support innovative and high quality research of international standing and include information on the capacity and track record of the applicants in delivering such high quality research. This should not rely on publication lists, but present evidence of recognised first-class research, innovation and collaboration.

Innovation - The proposal should present novel approaches to current research challenges and persuasive approaches to roadmap solutions. This should be in the context of the research theme defined in the technical appendix.

Originality - The proposal should demonstrate innovative approaches to problem solving with evidence of ability, creativity and vision and added value to current research in the field. The application should be focused toward addressing research challenges of the theme.

Objectives - The applicant should communicate an enthusiasm for collaboration and ability to contribute to a programme of research that delivers the objectives of the TSEC programme. They should demonstrate awareness of the drivers affecting the research agenda and the potential to contribute to the development of whole-systems approaches to energy issues.

Applicants for consortia will be informed of the outcome of their bids in January 2004 and if successful will be invited to a workshop in March 2004 to facilitate the formation of consortia partnerships. Attendance at the workshops will be mandatory for consortium members, including users and industrial collaborators. Following the workshops, consortium partners will be invited to submit EPSRC grant applications, which will be subject to rigorous peer review.

Applicants for Research Groups will be informed of the outcome of their bids by mid-March 2004 and if successful invited to submit full proposals by

mid-June. Assessment of full proposals will entail applicants being interviewed by the assessment panel in September/October 2004.

All other applicants will be informed of the outcome of their bids in February 2004 and successful applicants invited to submit full proposals as appropriate.

How to Apply

Expressions of Interest

Expressions of Interest must be submitted using the Research Councils' joint application form (available in Word or PDF versions) and (with the exception of proposals for Research Groups on Managing the New Uncertainties - see below) be accompanied by no more than four sides of A4 text (minimum font 12 pt), including diagrams, figures and charts etc. in support of the application. This should include any relevant information that will assist assessment of the project that is not covered in the sections of the application form. It should include

- Details of the track record of the applicant or business and the particular qualities they would bring to the proposal.

- Identification of the broad challenge which the applicant would seek to address or to which they would be able to contribute

- Definition of the perceived key research challenges within the theme.

- Indication of potential deliverables.

- Information on the collaborating organisation in terms of cash or in-kind support and proposed benefits from collaboration.

Expressions of interest for Research Groups under the 'Managing the New Uncertainties' theme must be submitted using the Research Councils joint application form. However instead of the four sides outlined above the form should be accompanied by the following information:

A research proposal of no more than 3,000 words outlining the main proposed elements of the proposed Group's research programme and how this would contribute towards the achievement of the objectives of the Towards a Sustainable Energy Economy Programme

Plus the following appendices:

- no more than 1 side of A4 (minimum font 12 pt) providing details of references cited in the research proposal

- no more than 1 side of A4 (minimum font 12 pt) giving details of the proposed strategies for involving non-academic users at all stages and outlining the potential for collaboration and/or co-funding

- no more than two sides of A4 (minimum font 12 pt) outlining the proposed management structure of the Research Group, including time commitments of the proposed Director(s) and abbreviated cvs for all named applicants.

- no more than one side of A4 (minimum font 12 pt) outlining the Group's strategy for contributing to the development of inter-disciplinary research capacity in the field.

In section E of the form, under Scheme applicants should state Consortium, Centre Group, Network, Collaborative proposal, or Capacity building, as appropriate; and under Call should insert 'TSEC call 1': followed by the appropriate theme name: Nuclear; Managing new uncertainties; Carbon Management, or Renewable energy.

As the majority of institutions have not yet registered with the Research Councils for electronic submission, in this call electronic submissions cannot be accepted. An original plus ONE copy are required in hard copy. Faxed copies are not acceptable.

All applications should be submitted to reach the NERC at the address below no later than 5pm on 19th January 2004. Personal callers may deliver applications during normal office hours only (9am - 5pm Monday - Friday). The Research Councils will reject late or incomplete submissions and those that do not comply with the application criteria set out above.

Receipt of applications will be acknowledged after the closing date. It will assist administration of the call if applicants do not telephone to enquire if their proposal has been received.

Applications and administrative queries should be addressed in the first instance to:

Dr Chris Baker (e-mail preferred)
Programme Co-ordinator
Science and Innovation Programmes
NERC, Polaris House, North Star Avenue
SWINDON, Wiltshire SN2 1EU.
Telephone 01793 411758.

Queries regarding the technical aspects of the Nuclear Power theme should be addressed to: Dr Peter Hedges, EPSRC, telephone 01793 444176. Queries regarding the application criteria or eligibility for the Nuclear Power theme should be addressed to the Associate Programme Manager Mr Robert Heathman, Room GFN, EPSRC, telephone 01793 444131.

Queries regarding the application criteria or eligibility for the Managing New Uncertainties theme should be addressed to Mr Paul Rouse, Senior Science and Development Manager, Research Training and Development Directorate (RTD), ESRC, at the above address, telephone 01793 413030, or Mr Oliver Moss, Science and Development Manager, RTD, ESRC, telephone 01793 413064.

Hi Ed and Keith

for your information, I attached the revision of the EOS article. In this version we added some lines about the data-overlap between the MBH and ECS records.

I also attached a figure showing a comparison between MBH and EsperFULL (using all data) and EsperSUB (without Tornetraesk and the Polar Urals).

Take care

Jan

Subject: CLIMATIC CHANGE needs your advice - YOUR EYES ONLY !!!!!
Date: Fri Jan 16 13:25:59 2004

Mike,

This is for YOURS EYES ONLY. Delete after reading - please ! I'm trying to redress the balance. One reply from Pfister said you should make all available !! Pot calling the kettle

black - Christian doesn't make his methods available. I replied to the wrong Christian message

so you don't get to see what he said. Probably best. Told Steve separately and to get more

advice from a few others as well as Kluwer and legal.

PLEASE DELETE - just for you, not even Ray and Malcolm

Cheers

Phil

Dear Steve et al,

I've been away this week until today. Although the responses so far all make valid points, I

will add my thoughts. I should say I have been more involved in all the exchanges between

Mike and MM so I'm probably biased in Mike's favour. I will try and be impartial, though, but

I did write a paper with Mike (which came out in GRL in Aug 2003) and we currently have a long paper tentatively accepted by Reviews of Geophysics. With the latter all 4

reviewers

think the paper is fine, but the sections referring to MM and papers by Soon and Baliunas

are not and our language is strong. We need to work on this.

Back to the question in hand:

1. The papers that MM refer came out in Nature in 1998 and to a lesser extent in GRL in

1999. These reviewers did not request the data (all the proxy series) and the code. So, acceding to the request for this to do the review is setting a VERY dangerous precedent.

Mike has made all the data series and this is all anyone should need. Making model code available is something else.

2. The code is basically irrelevant in this whole issue. In the GRL paper (in 2003 Mann and Jones), we simply average all the series we use together. The result is pretty much the same as MBH in 1998, Nature and MBH in 1999 in GRL.

3. As many of you know I calculate gridded and global/hemispheric temperature time series

each month. Groups at NCDC and NASA/GISS do this as well. We don't exchange codes - we do occasionally though for the data. The code here is trivial as it is in the paleo work.

MBH get spatial patterns but the bottom line (the 1000 year series of global temps) is almost the same if you simply average. The patterns give more, though, when it comes to trying to understand what has caused the changes - eg by comparison with models. MM are only interested in the NH/Global 1000-year time series - in fact only in the MBH work

from 1400.

4. What has always intrigued me in this whole debate, is why the skeptics (for want of a better term) always pick on Mike. There are several other series that I've produced, Keith Briffa has and Tom Crowley. Jan Esper's work has produced a slightly different series

but we don't get bombarded by MM. Mike's paper wasn't the first. It was in Nature and is well-used by IPCC. I suspect the skeptics wish to concentrate their effort onto one person as they did with Ben Santer after the second IPCC report.

5. Mike may respond too strongly to MM, but don't we all decide not to work with or co-operate with people we do not get on with or do not like their views. Mike will say that MM are disingenuous, but I'm not sure how many of you realise how vicious the attack on him has been. I will give you an example.

When MM came out, we had several press calls (I don't normally get press calls about my papers unless I really work at it - I very rarely do). This was about a paper in E&E, which when we eventually got it several days later was appalling. I found out later that the authors were in contact with the reviewers up to a week before the article

appeared. So there is peer review and peer review !! Here the peer review was done by

like-minded colleagues. Anyway, I'm straying from the point. Tim Osborn, Keith Briffa and I felt we should put something on our web site about the paper and directs people to Mike's site and also to E&E and the MM's site. MM have hounded us about this for the last four months. In the MM article, they have a diagram which says 'corrected version' when comparing with MBH. We have seen people refer to this paper (MM) as an alternative reconstruction - yet when we said this is our paragraph MM claim they are not putting forward a new reconstruction but criticizing MBH 1998 !! We have decided to remove the sentence on our web page just to stop these emails. But if a corrected version isn't a new or alternative reconstruction I don't know what is.

So, in conclusion, I would side with Mike in this regard. In trying to be scrupulously

fair, Steve, you've opened up a whole can of worms. If you do decide to put the Mann response into CC then I suspect you will need an editorial. MM will want to respond also.

I know you've had open and frank exchanges in CC before, but your email clearly shows that you think this is in a different league. MM and E&E didn't give Mann the chance to

respond when they put their paper in, but this is a too simplistic. It needs to be pointed

out in an editorial though - I'm not offering by the way.

I could go on and on

Cheers

Phil

At 10:36 15/01/2004 +0100, Christian Azar wrote:

Dear all,

I agree with most of what has been said so far. Reproducibility is the key word. If the Mann et al material (to be) posted on the website is sufficient to ensure reproducibility, then there is no compelling need to force them to hand it out. If not, then the source code is warranted. Also, even if there is no compelling need to make the source code public, doing it anyway would clearly be beneficial for the entire debate.

Yours,

Christian

Hi Art,

Sorry for the lack of response to your emails. Been over the top as usual on things. I go off to Tasmania and New Zealand on Jan 20 and return on Feb 15. Bhutan was a bit strange this time. I was sick most of the time, but we did get some useful stuff done nonetheless.

I am cc'ing this email to Gordon and Rosanne. I think that they would be interested in what you describe. They also know what climate data are available. I recall that Aklavik has a older record that was discontinued a few years back. It may be possible to merge Aklavik with Inuvik temperature records to cover most of the 20th century.

This sounds interesting. Are you measuring up all of the tree cores?
I wouldn't have the resources to do that without some technician
support, but I could participate in some dendroclimatic analyses of
the data with you.

I did ask Keith Briffa about this stuff. He is tied in closely with
much of the work that has been done in Fennoscandia and even over to
the Polar Urals. He also said that there has been some isotopic work
done on wood, but he wasn't sure about results. I suggest that you
contact Keith directly (k.briffa@uea.ac.uk) and maybe he can direct
you to sources of wood for your proposed study. It is interesting, if
a bit chancy in my estimation.

Malcolm seems to have done a good job sorting out these constituent sets , and I don't have anything to add other than agreeing that as a general principal , where possible, original chronologies should be used in preference to reconstructed temperature series (the latter having been already optimized using simple or multiple regression to fit the target temperature series). This applies not only to our western US reconstructions (which it should be stressed are based on very flexible curve fitting in the standardisation - and inevitably can show little variance on time scales longer than a decade or so) but also to the Tornetrask and Polar Urals reconstructions (each of which was based on ring width and density data , but standardised to try to preserve centennial variability - though the density series had by far the largest regression coefficients). There is though a question regarding the PCs of the Siberian network (presumably provided by Eugene?) . The correlation between density and ring width can get high in central and eastern parts of the network , so even though these are different variables , it might not be strictly true to think of them as truly independent (statistically) of the density chronologies we use from the Schweingruber network (there may also be a standardisation issue here , as the density chronologies were standardised with Hugershoff functions for our initial network work (as reported in the Holocene Special Issue) whereas your PC amplitudes may be based on "Corridor Standardisation" - which likely preserves less low frequency?) . These remarks are simply for clarification and discussion , and I too will wait on your response draft , though I would throw in the pot the fact that omitting the time dependent stuff would simplify the message at his stage. cheers

Keith

Mike - you are right that we should probably leave the network unchanged for this mss. In fact, however, as Keith indicated, the Vaganov data probably retained a fair amount of low frequency because of the use of the corridor method (i.e. were not "heavily standardized"). Cheers, Malcolm

Hi Ed and Keith

for your information, I attached the revision of the EOS article. In this version we added some lines about the data-overlap between the MBH and ECS records.

I also attached a figure showing a comparison between MBH and EsperFULL (using all data) and EsperSUB (without Tornetraesk and the Polar Urals).

Take care

Jan

From: Iain Brown <Iain.Brown@uea.ac.uk>
To: a.watkinson@uea.ac.uk
Subject: Inter-reg proposal update
Date: Thu, 29 Jan 2004 11:25:44 +0000
Cc: m.hulme@uea.ac.uk, s.jude@uea.ac.uk

Andrew,

Here is an update on the Inter-reg proposal, based upon the recent Oxford workshop.

Organisations involved:

EA, EN, Oxford ECI, Oxford Brooks (Planning), Alterra (Netherlands), Hampshire CC, Kent CC, Conservatoire de Littoral, Clare CC, Maynooth U., Tyndall

Funding:

Aiming for a 3 year project of 3-4 million Euros. Inter-reg 3B most closely fits project objectives but still unknown whether sufficient funds remain for this. Inter-reg 3C represents an alternative, but requires more high-level policy. Inter-reg deadline is April 29th. Other alternatives are LIFE and Framework VI.

Key issue:

Are Tyndall to be included as a Partner or a Contractor? Partners have more influence on project development but would require 50% matched funding (however this can be met through including other contributing R&D projects). Contractors do not need matched funding but may have to officially tender for sub-contract.

Proposed Work Packages:

1 Policy Review of spatial planning mechanisms for biodiversity (European, national, regional, local). How will this cope with climate change? Oxford Brooks & Oxford ECI to lead on developing this WP.

2 Broad-scale Review of impacts of climate change on biodiversity in NW Europe. To identify main drivers, issues and vulnerabilities on a network basis. Lead: Alterra, Oxford ECI, Tyndall

3 Coastal case studies - Hamble (England), Shannon (Ireland), Baie de Vaie (France). Objectives to evaluate local management issues with regard to simulation of future coastal evolution. Lead: EA, Hampshire CC

4 Terrestrial case studies - 2 regions: SE England, Limburg. Lead Alterra, ECI

5 Policy Development & Guidance - based on review of research outputs. Lead EN

6 Dissemination

Cross-cutting issues - stakeholder engagement, assessment/management of key habitats

Next steps - develop WPs, workplans and costing of proposal by 27th Feb.

Next meeting 4th/5th March, Oxford.

regards,

Iain

Mike,

In an odd way this is cheering news ! One other thing about the CC paper - just found another email - is that McKittrick says it is standard practice in Econometrics journals to give all the data and codes !! According to legal advice IPR overrides this.

Cheers

Subject: Re[2]: Stephen McIntyre
Date: Mon Feb 2 14:37:36 2004

Rashit

that sounds great - at least I am happy you are working on the sub fossil material still. I have done some work comparing the Swedish and Finnish long series after standard RCS detrending and there is good similarity at the century timescale for some considerable periods - but significant differences over some others , even allowing for uncertainty in the series These are only 300 km separated so this is an interesting indication of changes in continentality perhaps. I am also interested in extending the high-frequency density series before 1400 AD , to show earlier volcanoes , even though the spatial coverage is poor. It would be interesting to see your extreme year series - do you have a preprint of your paper? I would really like to get support to continue a wider collaboration , including other northern long series to produce wide scale integrated series . What is the latest state of your tree-line reconstruction , for periods earlier than you showed in the Holocene paper? I am still hoping such support may come again from Europe.

very best wishes

Keith

At 07:28 PM 2/2/04 +0500, you wrote:

Dear Keith,

it is very nice to hear from you.

We live and work in the old way. Stepan has been updated his woody vegetation descriptions in the Polar Urals to reconstruct dynamics of forest structure near upper timberline for the last century.

Because of some reasons (sometimes without any reasons) the work on constructing Yamal chronology is going not very well. Duration of chronology is now 7315 years (7314 BC - AD 2000). The last valuable field work has been realized in 2000, when we have collected 370 subfossil samples. Half of them have been dated. Now I successfully collect money for field work (for helicopter rent). I hope this field season will be fruitful. Meantime we have analyzed frost- and light-ring frequency in Yamal tree rings for the last 2100 years to reconstruct extreme events. The later half of this reconstruction, I hope, will be published this year in Palaeo3. Now I contracted (together with Stepan) to write by June something like textbook on tree-ring dating for archeologists (in Russian). Then I'm going to return to work on Yamal chronology. It would be pleasure to keep on our joint work.

Dear Keith,
it is very nice to hear from you.

We live and work in the old way. Stepan has been updated his woody vegetation descriptions in the Polar Urals to reconstruct dynamics of forest structure near upper timberline for the last century.

Because of some reasons (sometimes without any reasons) the work on constructing Yamal chronology is going not very well. Duration of chronology is now 7315 years (7314 BC - AD 2000). The last valuable field work has been realized in 2000, when we have collected 370 subfossil samples. Half of them have been dated. Now I successfully collect money for field work (for helicopter rent). I hope this field season will be fruitful. Meantime we have analyzed frost- and light-ring frequency in Yamal tree rings for the last 2100 years to reconstruct extreme events. The later half of this reconstruction, I hope, will be published this year in Palaeo3. Now I contracted (together with Stepan) to write by June something like textbook on tree-ring dating for archeologists (in Russian). Then I'm going to return to work on Yamal chronology. Dear Keith,

attached manuscript concerning frost and light rings has been submitted to Paleo3 special issue (PAGES conference in Moscow in 2002). I'm still waiting for final decision.

Meantime we prepare next version of extremes reconstruction (on the base of Yamal data only) for the last 2100 years using frost, light, missing and very narrow rings. Unfortunately, I could not find time to prepare even draft version of this paper. I can send to you the picture and list of the "extreme" years for this period, if you are interested. Now analysis is going on, little by little. Most probably, we will prepare for publication data for longer reconstruction (up to 4000 years).

As to tree-line reconstruction, we have almost no progress. To get more reliable reconstruction we need more samples from sites northwards of 68°N. In 2002 we have sampled subfossil wood in this area. However, without success (only 30 samples, only 5 of them I was able to date). Now we have in all 30 dated samples from the area to the north of 68°. Attached .pcx files show reconstructions that have been published before in the local publications. Only one correction we can do after 2002 field season, namely that big shift of tree line took place after 2420 BC. Hope I will succeed finally in dating of rest of samples to improve reconstruction.

Dear Keith,
attached file contains results of analysis of anomalous rings in Yamal material for 100BC - 2000 AD.

I forgot to inform you about one more thing. We have organized data bank of Russian tree-ring chronologies. Unfortunately (for you), in Russian.

<http://ipae.uran.ru/dendrochronology/>

(and then click on the icon in the bottom (in center) of page).

This databank is made for archeologists and people that need to date woody constructions and etc. The aim is to give them information about where and what kind of chronologies there are in Russia. For some locations chronology is available or links to other databanks, for others - information only. Site is still filling up. If you are interested to see you can ask Vladimir Shishov to translate. By the way, you can remind him about my request to place chronologies of their lab in this bank.

Dear All,

So now it seems that we're separating 'providing the code' from
'running the code'. I

can't

see the purpose of one without the other. Even if Mike complies I
suspect there will need

to be several sessions of interaction, which neither side will be
very keen on. As I said

before

I know the code will involve lots of combinations (for different
periods with different

proxies).

Also I would expect, knowing the nature of the PC-type regression
approach, that there

will

be library routines. If the code is sent, there needs to be
conditions. We don't want

McIntyre

(MM) to come out and say he can't get it to work after a few days.

So, it is far some simple. I'm still against the code being
given out. Mike has made

the

data available. That is all they should need. The method is detailed
in the original

paper -

in the online (methods) and also in several other papers Mike has
written.

As an aside, Mike is now using a different method from MBH98.
Also, as an aside,

whilst we've been deliberating, MM have submitted another comment on
MBH98 to another

journal. In this they say they have a program that replicates MBH98
(although it isn't

very convincing that they have it exactly right, as they never show a
like for like

comparison) , but

most of the comment goes on about the results being different due to
different

combinations of
proxies. The latter isn't surprising.

It might appear they want the code to check whether their version works properly. If

this
is the case, then there are issues of IPR. So, if they get the code,
how do we stop them
using it for anything other than this review.

Cheers

Phil

At 11:40 04/02/2004 -0800, Peter H. Gleick wrote:

Yes, excellent point. This should be what we do. Further, we can
point out that we've
bent over backward here and provided more than typically necessary
in order to satisfy
persistent but inappropriate demands.

Peter

At 08:46 PM 2/4/04 +0100, Mearns Linda O wrote:

Peter et al.,

Thanks for reminding me about the new email list.

My point about the code is still that 'providing the code' can be
interpreted alot of ways. I have thought about this, and imagined
if in

one of my larger and more complex projects, I was asked to provide
all
code. I could do that just by sending the pieces with a summary
file

explaining what each piece was used for. It still theoretically
allows

someone to see how coding was done. And I do think that is a far
sight

easier than providing stuff that can be run, etc. I am suggesting
that

one could do the minimum. Then the point is, one isn't faced with
garish

headlines about 'refusal to provide code'. I think it is harder to
come

up with a garish headline about 'refusal to provide completely
documented

code with appropriate readme files and handholding for running it'.

Linda

Dear Tas,

Thanks for the email. Steve McIntyre hasn't contacted me directly about Law Dome (yet), nor about any of the series used in the 1998 Holocene paper or the 2003 GRL one with Mike. I suspect (hope) that he won't. I had some emails with him a few years ago when he wanted to get all the station temperature data we use here in CRU. At that time, I hid behind the fact that some of the data had been received from individuals and not directly from Met Services through the Global Telecommunications Service (GTS) or through GCOS.

I've cc'd Mike on this, just for info. Emails have also been sent to some other paleo people asking for datasets used in 1998 or 2003. Keith Briffa here got one, for example. Here, they have also been in contact with some of Keith's Russian contacts. All seem to relate to trying to get series we've used. In the Russian case, issues relate to the Russian (Rashit Hantemirov) having a paper out with the same series Keith used (for the Yamal Peninsula). Series are different for two reasons. One Keith used the RCS standardization method and secondly Rashit has added some series since Keith got the data a couple of years ago.

I'll just sit tight here and do nothing. Mike will likely do the same, but we'll expect another publication in the nearish future.

As for the series for LD you sent us, we used it in the paper for Reviews of Geophysics. This paper has had 4 good reviews and we've just sent back a revised version. This will likely get reviewed by 1 or 2 of the same reviewers of the editor, but I think it will come out this year some time. When it does, we will put all the series onto a web site. Hope this is OK with you. It will unlikely be before our summer months.

Cheers
Phil

At 17:56 09/02/2004 +1100, you wrote:

Dear Phil,

What you will find below is (in reverse chronological order) an email interchange between Steve McIntyre and myself. He has been asking for LD data for a while (since your GRL paper came out) and to my chagrin, I have put him off once already, for reasons I spell out below. For your information, I am close to submitting the full LD isotope record, which I hope to present at SCAR Bremen, along with some interesting spectral analyses and comparison to EPICA Dome C.

Anyway, I am aware of McIntyre's controversial history and am trying to handle things in a non-inflammatory way. He seems not to be troubling me over my own delay, but has asked for data that was used in your Holocene paper of 1998. For this, I have referred him to you. I expect he wants to replicate your synthesis, and so he should use the identical data set, and I give you permission to pass on whatever it was I gave you for that work - with the caveat that it is representative of where the LD proxy record was in 1997, not 2004. I leave it to you to decide how to deal with this - you may prefer to ignore the issue, and I would understand.

Let me know if there is anything I can do to assist.

Cheers,
Tas

Dear Stephen,

I suggest you ask Phil Jones for a copy of that older data set. Jones et al cite Morgan and van Ommen 1997, although that data set was heavily smoothed (gaussian of rms=13 years from memory), so the one they show is not a direct version of Morgan and van Ommen 1997. I think that I provided them with a high resolution version, and from their notation, it seems that they are using a November-April subset, but you would have to ask Phil - especially if what you seek is to replicate their analyses. Apart from anything else, our set has been continually in a state of development, which is why I have not wanted to widely circulate it until now. Over this period we have had made new measurements (which improved our layer counted dating and filled the gap that you see in Jones et al.), retrieved more cores using better technology and derived a robust gas-tied flow-model that dates the core to 90ky. Now that the new development has ceased, we will soon be releasing the full data set, as I have indicated to you. This is the set I would want to see in wider use, and it is worth noting that it is essentially the same as the portion used by Mann and Jones in their GRL paper in 2003.

All the best,

Tas

Subject: RE: Law Dome O18

Dear Stephen,

The 18O data used in Mann and Jones 2003 was provided as an advance copy in 2003, and you are welcome to have access to it and it will certainly be placed in public archives.

The data in question is part of the full 90 ky isotope record from Law Dome, for which a peer-reviewed dating scale has only recently been published (actually it is in press see van Ommen et al, in press Annals of Glaciology 39 at [9]<http://www.antrc.utas.edu.au/~tas/home/openaccess.html#vanommen04LD1>). Now this job is done, I am finalizing a paper that will allow me to release the isotope record more widely.

It is this next paper that controls the timeframe for release to you and archives. While I should await peer review for a release to the archives, I am happy to pass on a copy of the data set to you on an advance basis as soon as the paper is submitted I expect in a couple of months. You will appreciate that at this time of the year, we in the south are in our vacation season, not to mention dealing with our Antarctic Summer field program, so I thank you for your patience. Do check back with me in a while if you dont hear more.

Regards,

Tas

Mike,

These were two simple ones to provide. Also Tas told him I had one of them. I guess these are the ones that aren't available on web sites.

Anyway, it is done now. If he starts asking for them in dribs and drabs, I'll balk at that.

Ben waded in with very positive comments re the CC issue. Steve's going to find it very hard to ask you to send the code. Those that say on the CC board that you should send the code, have little idea what is involved. Most are on the social science side.

Cheers

Phil

At 10:19 09/02/2004 -0500, you wrote:

HI Phil,

Personally, I wouldn't send him anything. I have no idea what he's up to, but you can be sure it falls into the "no good" category.

There are a few series from our '03 paper that he won't have--these include the latest Jacoby and D'Arrigo, which I digitized from their publication (they haven't made it publicly available) and the extended western North American series, which they wouldn't be able to reproduce without following exactly the procedure described in our '99 GRL paper to remove the estimated non-climatic component.

I would not give them *anything*. I would not respond or even acknowledge receipt of their emails. There is no reason to give them any data, in my opinion, and I think we do so at our own peril!

talk to you later,

mike

At 02:46 PM 2/9/2004 +0000, Phil Jones wrote:

Mike,

FYI. Sent him the two series - the as received versions. Wonder what he's up to? Why these two series ? Used a lot more in the 1998 paper. Didn't want the Alerce series.

Must already have the Tassy series from Ed. I know Ed has a more recent series than we used in 1998. Got this for the 2003 work.

Cheers

Phil

Ben,

Every now and then - generally around an England game (probably now as we've just drawn with Portugal) or lamenting the fall of Liverpool, I get emails and sometimes phone calls from Pete Mayes !! Pete wants to get back into climate change and do some comparisons between real world data and some models. It is a pity he wasn't this keen, when he first went to the US !

Anyway I suggested he contact you. He has but he's not got a reply. I guess you're busy and/or don't know how to reply. I'm sure he doesn't know what he really wants. I gave him some references etc to look over and your name/email - so SORRY !!!!

I guess I'll see you just after Easter. Will you be here for the HC meeting as well as IDAG?

It will be good to see Tom in Oxford - he should liven up the IDAG discussions.

Hope all is well with you and Nick !

Cheers

Phil

PS I see Steve has replied to MM re the MBH review. This nearly got out of hand - it still could. Appalling paper in GRL in the Feb04 issue - Mike Mann's written a response. Clearly another case of the GRL editor's having no idea of the science. Who in their right mind would accept that for publication. Nowhere on the CRU site does it say that HadCRUT2v is the IPCC data. According to the HC the IPCC data is the OA version HadCRUT - no v, no 2.

The data is on the HC web site. There is a link to it from the CRU site. When getting data from the CRU site we ask people to refer to some of the papers and to use the dataset names. Soon et al didn't do either. Paper attached as I have it.

Just had a paper accepted by Reviews of Geophysics with Mike Mann on the climate of the last 2k years. Expecting flak for this, but it had 4 very positive reviews.

For some inane reason I put my name forward to do the chapter on atmospheric obs. for AR4. Hope I don't get picked.

Mike,

Just agreed to review a paper for GRL - it is absolute rubbish. It is having a go at the CRU temperature data - not the latest vesion, but the one you used in MBH98 !! We added lots of data in for the region this person says has Urban Warming ! So easy review to do.

Sent Ben the Soon et al. paper and he wonders who reviews these sorts of things. Says GRL hasn't a clue with editors or reviewers. By chance they seem to have got the right person with the one just received.

Can I ask you something in CONFIDENCE - don't email around, especially not to Keith and Tim here. Have you reviewed any papers recently for Science that say that MBH98 and MJ03 have underestimated variability in the millennial record - from models or from some low-freq proxy data. Just a yes or no will do. Tim is reviewing them - I want

to make sure he takes my comments on board, but he wants to be squeaky clean with discussing them with others. So forget this email when you reply.

Cheers

Phil

Ben,

Thanks for the plots and keeping me up to date. The ERA-40/CRU comparisons are quite interesting. I'm hopeful Adrian will write up a summary for publication in addition to an ECMWF report.

This sort of thing is important wrt IPCC and also papers such as Kalnay and Cai.

I'm also working with Russ Vose and others at NCDC to get a comparison of CRU/GHCN and NASA datasets in GRL. NCDC have used their first difference technique with CRU data. Differences are very, very small due to data and the technique doesn't matter much either. All seems to boil down to how the global average is defined. Calculated as one domain as NCDC (and until recently the HC as well) want to do it, it is biased to the NH. If you do it the CRU way ($G=0.5(NH+SH)$) then it looks much more like an OA version of HadCRUT2v that the HC have just produced. Been saying this for years as has Tom, so no surprises. Finally got the HC to realise it, now just need to convince NCDC.

NCDC will also have a new 5 by 5 deg gridded dataset of Tx and Tn soon, right up to the present. Need to compare this with ERA-40.

Cheers
Phil

Dear Adrian,

Thanks very much for sending me your comparison of surface air temperature changes in CRU and ERA-40. I've been looking at a related issue - the correspondence between 2m temperature changes in ERA-40 and PCM.

Here's the background to this work. Increasingly, there is some interest in the problem of identifying anthropogenic climate change at regional scales. I have to give a brief talk on this subject tomorrow. In preparing for this talk, I decided that it would be useful to show how signal and noise change as a

function of spatial scale. I looked at the behavior of 2m temperature in the four individual realizations of the PCM "ALL forcings" experiment (the same experiment that we analysed in our joint Nature paper). For each realization, I computed spatial averages over the globe, the Northern Hemisphere, and the western United States (30-50N, 126W-114W). These spatial averages were then expressed as anomalies relative to climatological monthly means over 1979-1999. The orange shading in the three panels of the figure entitled "tas_tseries3.ps" is a measure of the between-realization variability in PCM. The envelope is simply the range (during any given month) between the maximum and minimum values of the four realizations. This range was then low-pass filtered. The solid red is the low-pass filtered ensemble mean.

To facilitate comparison with PCM data, I've defined 2m temperature anomalies in ERA-40 in the same way (i.e., relative to climatological monthly means over 1979-1999), and have used the same low-pass filter. One can then ask whether the 2m temperature changes in ERA-40 are consistent with those in PCM - in other words, are they encompassed by PCM's envelope of possible climate responses to combined anthropogenic and natural forcing?

They are. Surprisingly, this consistency occurs not only at the global-mean level, but also for the NH and western U.S. For the global-mean and the NH, the ERA-40 2m temperature changes are outside PCM's envelope of 2m temperature changes during the first 5-10 years of the reanalysis. After the late 1960s, however, the ERA-40 2m temperature changes are entirely consistent with those in PCM. Over the western U.S., 2m temperature changes in PCM and ERA-40 are consistent throughout the reanalysis period.

Such qualitative consistency, while interesting, is no substitute for formal, pattern-based fingerprint detection studies at global, hemispheric, and regional scales. For example, an overestimate of the regional-scale variability of 2m temperature by PCM could explain why PCM's 2m temperature changes over the western U.S. fully encompass the ERA-40 result (see panel C). On the other hand, there is some real similarity in the low-frequency component of the 2m temperature changes in ERA-40 and PCM (look at the similar responses to Agung, Chichon, and Pinatubo in panel B!)

The bottom line is that PCM's 2m temperature changes are reasonably consistent with those in ERA-40, even at sub-global spatial scales. This suggests that formal regional-scale detection work might be useful. If you are interested, perhaps we could collaborate on such work. A collaboration would also involve the PCM group at NCAR (to whom I'm copying this email).

The second figure that I've appended shows the global-mean changes in synthetic MSU channel 2 temperatures in PCM and ERA-40. The message is pretty much the same as for 2m temperatures: PCM's "envelope" of possible changes in tropospheric temperatures largely encompasses the ERA-40 results, except during a few large El Nino and La Nina events. Once again, there is surprising similarity in the low-frequency component of the model and reanalysis T2

changes.

It would be fun to take these simple comparisons a little further!

With best regards,

Ben

Dear Jorge,

Happy for you to use me in an additional attempt to get some Mexican support to come to CRU next year. What exactly do you need? Send me an example of what you want? Life is very busy here at the moment as I'll be away for several meetings over the next 6 weeks and I must prepare some material for most of them.

GKSS is just one model and it is a model, so there is no need for it to be correct. I am also aware that Ed Cook is revising the ECS curve in a paper he's submitting to Quaternary Science Reviews.

Remember that if ECS (and GKSS) are correct then the climate is more sensitive to external forcing (the factors that cause past changes/variability). If the climate is more sensitive then the likely changes in the future will be greater. The curves that we've produced here (and also Mike Mann's) suggest a climate sensitivity of about 2.5 deg C for a CO2 doubling. Getting volcanic forcing right in the past (along with solar)

are crucial in any study.

Cheers

Phil

At 12:22 12/03/2004 -0600, you wrote:

Dear Dr. Jones:

I am very happy because I went to a Workshop in Kona Hawaii (with support of NASA-CRCES after to gain a contest with a review paper about global temperature reconstructions, it was a different version of the paper that you have read). There I met with Dr. Michael Mann. Mann was very kind with me, however when he did know my work he changed his attitude. I met there also Dr. Hans von Storch who presented a global temperature reconstructions with a AOCGCM with natural and anthropogenic forcings. His results agree more or less with ECS, and my results. I am in contact with the GKSS group in order to compare and share information.

However, the key point of my studies, as you have pointed out, is to justify that the background Ice Albedo (without volcanic activity) from polar caps could be considered as a proxy. I have contacted Dr. Hammer and Dr. Crowley to have information and advice.

In order to continue this kind of studies I would like to propose you again (as we have tried last year) to ask support from the AMC (Mexican Academy of Sciences) to support a visit to CRU-UEA next year to continue my work, with your help and advice, about global temperature for the Holocene. I will

need only an official invitation for my visit. It would be in March 2005 for 3 or 4 weeks.

Also, I am asking support to travel to Japan this year (this fall), however I would like to stop in England a week, in order to visit CRU-UEA and to continue our collaboration.

I would like to know your opinion,

cheers,

Jorge

Date: Wed Mar 31 09:09:04 2004

Mike,

Yes, but not had a chance to read it yet. Too much else going on. Ed has a paper reworking Esper et al. as you'll know. If you're going to Tucson, I suggest you talk to Keith about it then - don't email him as he's too busy preparing to go and marking essays.

Jan is in one of our EU projects. Seems that Keith thinks Jan is reinventing a lot of Keith's work, renamed the RCS method and much more. Jan doesn't always take in what is in the literature even though he purports to read it. He's now looking at homogenization techniques for temperature to check the Siberian temperature data. We keep telling him the decline is also in N. Europe, N. America (where we use all the recently homogenized Canadian data). The decline may be slightly larger in Siberia, but it is elsewhere as well.

Also Siberia is one of the worst places to look at homogeneity, as the stations aren't that close together (as they are in Fennoscandia and most of Canada) and also the temperature varies an awful lot from year to year.

Recently rejected two papers (one for JGR and for GRL) from people saying CRU has it wrong over Siberia. Went to town in both reviews, hopefully successfully. If either appears

I will be very surprised, but you never know with GRL.

Cheers

Phil

Cheers

Phil

At 11:20 30/03/2004 -0500, you wrote:

Phil,

Have you seen this piece of crap by Esper?

The JGR paper, which Scott is supposed to be finalizing, demonstrates quite convincingly that the greater amplitude of Esper et al is due to spatial and seasonal sampling,

Scott and Mike,

It's been a long week catching up from 3 weeks away. Getting another email from McIntyre asking me for paleo data series I don't have (I'm not going to reply, by the way even though he calls me Phil and other emails he sends me are to Dr Crowley and Dr. Briffa who've also not replied) reminded me that I agreed with Mike to put together as many of the series from the RoG paper onto a page on the CRU web site.

So, with this in mind, can you send me the data for the various plots. I checked the paper and Fig 1 doesn't need anything, so this leave Figs 3 (on the boreholes), 5 (with the various NH/SH/Global series) and 8 (with all the various model runs).

Figure 3 should be trivial as borehole data are only every 50 years. For the other 2 plots

I'm after the annual values of each series and the smoothed ones that get plotted. Hope this

won't take too long to do. I'm going to send emails to a few people to check we can make the data available (mainly the modellers, but also Tas van Ommen).

Cheers

Phil

Subject: RoG paper

Date: Fri May 7 16:43:21 2004

Dear Tas and Caspar,

Attached is the proof version of the RoG paper with Mike Mann. This is about 99.99% the final one. Mike and I sent back a few small changes to AGU a month or so ago. Keep this to yourself for a while yet - I would expect the paper out sometime in the July/August period.

Many of us in the paleo field get requests from skeptics (mainly a guy called Steve McIntyre in Canada) asking us for series. Mike and I are not sending anything, partly because we don't have some of the series he wants, also partly as we've got the data through contacts like you, but mostly because he'll distort and misuse them.

Despite this, Mike and I would like to make as many of the series we've used in the RoG plots available from the CRU web page. Can we do this with the series we've got from you? You don't have to do anything, except to reply yes or no !

Cheers

Phil

From: f037 <M.Hulme@uea.ac.uk>
To: Aiguo Dai <adai@cgd.ucar.edu>
Subject: denial or delusion? ... Aiguo's response
Date: Sat, 8 May 2004 07:59:14 +0100
Cc: <jprospero@rsmas.miami.edu>, <m.hulme@uea.ac.uk>, <p.jones@uea.ac.uk>, <plamb@ou.edu>, <trenbert@cgd.ucar.edu>

Dear Aiguo,

You've done a great job in putting this together so quickly and clearly. I have a couple of additional comments to make on it, but can't do so until Tuesday. You (we?) might also like to think of the reply being multi-authored, including Phil, Pete, Kevin, Joe and myself.

I must say that when I first read this paper a couple of weeks ago I wrote it off as so bad (so, so bad) that it didn't even deserve a response. To pretend that the Sahel drought didn't happen (i.e., a pure artifact of wrongful use of rainfall data) is the most astounding assertion, almost on a par with holocaust denial. Try putting that proposition to the millions of inhabitants of the Sahel in the 1970s, 1980s and 1990s, many of whom died as a direct consequence and whose livelihoods were devastated. Adrian Chappell may never have visited the region, but I know Clive Agnew has (many times) - and he should know better. I did my PhD research in the region in the early 1980s and I know exactly what the rainfall conditions were like and how much ordinary people suffered as a consequence. My PhD was on rainfall variability and local water supplies in Sudan and I visited and talked to many villagers in the region.

Anyway, Phil first suggested that a corrective reply was needed and I can see the value of doing so, especially with IPCC AR4 approaching. It just seems to me such a shame that such poor science is being done by some people - in this case I don't think there is a deeper motive on the part of Chappell and Agnew than pure delusion and incompetence - and, worse, that a journal like IJC will publish it.

Thanks again for your efforts,

Mike

Attachment: volc.doc

Dear Sarah,

Ben and I have had some long discussions about this paper, and I have made quite a few changes as a consequence. Most of these are minor -- but I realized that my statement that the peak cooling depended logarithmically on the sensitivity was potentially confusing. For this to be the case one has to have a relationship like

$$T_{\max} = A + B \ln(S)$$

which implies odd results for very low sensitivity. Instead, I have fitted a relationship of the form

$$T_{\max} = A [S^{**n}]$$

which gives $T_{\max} = 0$ when $S = 0$.

I have fitted a similar relationship to the decay time results, and I have done the same for the LG98 results. All this information has been added to the manuscript. It helps in understanding the differences between us and LG98.

I had hoped to send this off earlier this week, i.e., before I go to Buenos Aires (tomorrow), but I never received the copyright form from you. Then I remembered that you were at that IPCC meeting in Ireland. So I have asked Liz Rothney to send the ms off next week as soon as she gets the copyright form from you. So please fax this back (303 497 1333) as soon as possible.

Best wishes,
Tom.

Dear Keith,

I wish I could say that updating the Russian data is on the front burner for us right now, but I'm afraid it's not. I'm having to plan some proposals and have been pulled off part of my normal CDIAC work for about 6 months to work on a special project. And in our small group, I'm the only climate guy (and the one that has done the Russian work thus far). Thus, the first suggestion I have is to discuss the data with NCDC; perhaps the best person to start with would be Pasha Groisman. Years ago, when I did the Russian work, the data were actually transferred from Russia to NCDC and then on to us, so I wouldn't be surprised if NCDC was holding updated data or at least could get ahold of data relatively easily. Perhaps you've already corresponded directly w/Slava Razuvaev or one of his colleagues at RIHMI-WDC? I'm afraid it's been quite a while since I've spoken w/Slava.

Wait, maybe there is another way.... I've just remembered about NCDC's Global Daily Climate Network:

[1] <http://www.ncdc.noaa.gov/oa/climate/research/gdcn/gdcn.html>

I have not learned much about these holdings, but if you check it out perhaps they've incorporated more recent data daily into this database for the FSU.

I sure hope so.

I'm sorry that I cannot be of more help at this time. With any luck CDIAC can turn its attention to updates of these data in 2005.

Regards,

Dale

Subject: Global change and ecosystems
Date: Thu, 17 Jun 2004 16:39:42 +0100

2. Call for proposals - Thematic call in the area of 'Global change and ecosystems'.

OJ C159 (16.06.2004) p.3
Deadline for submissions: 26.10.2004

Activity: Priority thematic area 'Sustainable Development, Global Change and Ecosystems'; Sub-priority 'Global Change and Ecosystems'.

Call identifier: FP6-2004-Global-3

Total indicative budget: EUR 205 million

Areas called and Instruments:

- Area 6.3.I: Impact and mechanisms of greenhouse gas emissions and atmospheric pollutants on climate, ozone depletion and carbon sinks (IP, STREP, CA)
- Area 6.3.II: Water cycle, including soil related aspects (IP, STREP, CA)
- Area 6.3.III: Biodiversity and ecosystems (IP, STREP, CA, NoE)
- Area 6.3.IV: Mechanisms of desertification and natural disasters (IP, STREP, CA)
- Area 6.3.V: Strategies for sustainable land management, including coastal zones, agricultural land and forests (IP, STREP, CA)
- Area 6.3.VI: Operational forecasting and modelling including global climatic change observation systems (IP)
- Area 6.3.VII: Complementary research (IP, CA)
- Area 6.3.VIII: Cross-cutting issue: Sustainable Development concepts and tools (STREP, CA)
- Area 6.3.IX: Specific Support Actions (SSA)

I'll leave it up to you then.

Phil

At 16:04 18/06/2004 +0100, David Viner wrote:

Phil

Err! yes i think this would be good to get involved.

D

On 18 Jun 2004, at 15:40, Phil Jones wrote:

Dave and Clare,

I am presuming we (CRU) don't want to get involved with this.

Cheers

Phil

Subject: Proposal for a new Tyndall-led European research initiative

Date: Fri, 18 Jun 2004 15:16:20 +0100

Organization: University of East Anglia

X-Mailer: Microsoft Outlook, Build 10.0.3311

Importance: Normal

Dear Colleague,

The Tyndall Centre is intending to lead a bid for a large EU research project (ca 12-15 million Euros in the initial bid) on climate change adaptation and mitigation strategies in Europe. The call was announced this week with outline bids (ca. 20 pages) due by October (3rd call of the sixth framework programme, FP6).

Please find attached a copy of an invitation that has been sent out to a key set of European partners. This provides a little further information on the proposed scope and content of the project. We will be holding a planning meeting with European partners from the evening of Monday 19th July to end of Tuesday 20th July 2004.

You are receiving this email because we thought that you might have some interest in participating in this project. We would therefore like to hold an internal planning meeting of all interested Tyndall-linked researchers on the 19th July (starting at lunchtime; ca 3-4 hours long). Please let us know by 25th June, if you would like to take part in this internal planning meeting; and also whether you would like to make a short presentation at the meeting, about how your work with the Tyndall Centre might contribute. If you cannot attend on the 19th but are nevertheless interested in contributing to the proposal, please also let us know.

Warm regards,

Mike Hulme

John Schellnhuber

From: Phil Jones <p.jones@uea.ac.uk>
To: "Michael E. Mann" <mann@virginia.edu>
Subject: HIGHLY CONFIDENTIAL
Date: Thu Jul 8 16:30:16 2004

Mike,

Only have it in the pdf form. FYI ONLY - don't pass on. Relevant paras are the last 2 in section 4 on p13. As I said it is worded carefully due to Adrian knowing Eugenia for years. He knows they're wrong, but he succumbed to her almost pleading with him to tone it down as it might affect her proposals in the future !

I didn't say any of this, so be careful how you use it - if at all. Keep quiet also that you have the pdf.

The attachment is a very good paper - I've been pushing Adrian over the last weeks to get it submitted to JGR or J. Climate. The main results are great for CRU and also for ERA-40. The basic message is clear - you have to put enough surface and sonde obs into a model to produce Reanalyses. The jumps when the data input change stand out so clearly. NCEP does many odd things also around sea ice and over snow and ice.

The other paper by MM is just garbage - as you knew. De Freitas again. Pielke is also losing all credibility as well by replying to the mad Finn as well - frequently as I see it.

I can't see either of these papers being in the next IPCC report. Kevin and I will keep them out somehow - even if we have to redefine what the peer-review literature is !

Cheers

Phil

Mike,

For your interest, there is an ECMWF ERA-40 Report coming out soon, which shows that Kalnay and Cai are wrong. It isn't that strongly worded as the first author is a personal friend of Eugenia. The result is rather hidden in the middle of the report.

It isn't peer review, but a slimmed down version will go to a journal. KC are wrong because

the difference between NCEP and real surface temps (CRU) over eastern N. America doesn't happen with ERA-40. ERA-40 assimilates surface temps (which NCEP didn't) and doing this makes the agreement with CRU better. Also ERA-40's trends in the lower atmosphere are all physically consistent where NCEP's are not - over eastern US.

I can send if you want, but it won't be out as a report for a couple of months.

Cheers

Phil

Doug,

Maybe Steve sent you the two emails I've resent. Ignore my ramblings at the end of one, but I was getting a little fed up. The Legates email is at the end, in case you're interested.

The pdf is worth a read. Odd that he writes a press release, then starts working on a paper.

We've very occasionally written a press release, but only after the paper has come out.

I tried to explain the 'missing' rings. They aren't missing, but due to the samples not being right for density measurements. All Schweingruber's chronologies are constructed this way - traditional ring width measurements aren't made. Some of the Russian groups he's worked with have added extra ring width cores and sometime get longer series, but all the data Keith and I work with is from Fritz, so if density is missing, then RW is also.

Fritz did almost all the coring - 99% of the sites. We only help coring on a couple of occasions.

This comes from alignment tracking as you say, but Fritz also says it is partly due to the need to extract the lignin and to avoid resin. When we cored together, he was always saying we weren't doing it properly getting twisted cores. I'm not a proper dendro person,

as I only got into this because of Keith - it may not be lignin, but something has to be extracted with solvents.

The Polar Urals site was collected by Fritz and Stepan Shiyatov. There are living trees back to the 1500s and then stumps at a slightly higher elevation. Stepan has been back more recently and regeneration is occurring at higher levels, but it is taking time. Tree lines

take a while to respond to the recent warmth in some regions. Once the trees are established

and not killed by frosts/snow in winter they survive even if it gets cooler. I discussed this

in a review paper in RoG attached. The section on the issue is brief.

All the cores were collected over a couple of days. Fritz made a mistake with the labelling

for one core and that explains the 400 years of missing values. Someone at WDCP must have combined the cores with the same ids. Dendro people are always looking for the oldest trees and we kept the earliest series in. Steve seems to have a thing about these and the 10th and 11th centuries, but they are correctly dated. Fritz uses loads of plots and pointer years and doesn't make mistakes normally. There is a very distinct year at

AD 1032. Fritz is also cross dating with LWW and EWW and other features and not just on RW. I say not just, he normally does with density. At the coring stage Fritz had no idea

of the ages of the stumps (well just the number of years). There may have been samples off the front that couldn't be dated at all, for all I know. I suspect though they are roughly

the same calendar age, as the site has distinct dates for the start of trees, which represent

regeneration periods. Maybe you can try and explain the tree-line argument to Steve.

When he had to omit parts of cores, he was always able to know where the two parts sat in the sequence. We need to keep them together to do things like RCS.

Anyway, I have to go home - it's been very wet lately and the grass has grown. The lawn must be mowed when the sun shines.

Keep pushing that he should write up what he does (and Ross) in proper journals. E&E and Climate Research are not read by many now. I only look at them when I get alerted and I remain exasperated.

Cheers

Phil

Legates email

Phil Jones has made a valid point in that some of the articles cited in my critique do not 'directly' address problems with Mann and Jones (MJ) but rather, address problems with earlier works by Mann, Bradley, and Hughes (MBH) and other colleagues. Fair enough - I have changed the critique to reflect that fact. The revised version has been posted since July 19 at:

[1]<http://www.ncpa.org/pub/ba/ba478/ba478.pdf>

However, I still contend that most of my original arguments - namely, the problems with the shaft, blade, and sheath - apply equally to Mann and Jones as well as the other Mann et al. manifestations of the 'hockey stick'.

MJ incorporate data from a number of the same sources as those used by MBH; for example, Mann's unpublished PC1 from the western North American tree-ring data, Cook's Tasmanian tree rings, Thompson's Quelccaya and Dunde ice core oxygen isotope records (the latter embedded in Yang's Chinese composite), and Fisher's stacked Greenland ice core oxygen isotope record. Calibration and verification of MJ includes the flawed MBH curve. Thus, any errors in MBH effectively undermine the calibration-verification results of MJ, leaving this study unsupported and any problems with the underlying common proxies identified in critiques of MBH will also result in identical problems in MJ.

My criticism regarding the blade is that 0.6 deg C warming for the last century is noted by the IPCC whereas MJ (and other M et al representations) have up to 0.95 deg C warming in their observed record.

See MJ's figure 2 where for the global and NH reconstruction, their estimates for 2000 exceed +0.4 and +0.5 (nearly +0.6), respectively. MJ's NH curve is included in the attached graph. Thus, I stand by my criticism of MJ on this point, which is more egregious in MJ than other M et al representations.

>From Jones: "The trend over the 20th century in the Figure and in the instrumental data. IPCC quotes 0.6 deg C over the 1901-2000 period. Fact - but Legates is eyeballing the curve to get 0.95 deg C. A figure isn't given in Mann and Jones (2003). Take it from me the trend is about the same as the instrumental record."

Funny, but there IS a figure in MJ - see their Figure 2. As for me 'eyeballing' an apparently non-existent curve, I attach a figure from Soon et al. (2004) that contains a portion of MJ's Figure 2 to allow others to decide for themselves whether MJ suggest a twentieth century warming of 0.6 deg C or 0.95 deg C. Moreover, maybe someone can explain why every time Mann and his colleagues draft another curve, the temperature in 2000 gets warmer and warmer after the fact...

My criticisms regarding the sheath (largely from a paper on which I am working) stem from the characterization of the uncertainty by MJ that arises solely from the 'fit' statistics to the 1600-1855 period using cross-validation with, not observations, but composites of three previously compiled reconstructions, including that developed by MBH - the focus of known flaws and errors in the shaft. Note that some of the same data are used in both MBH and MJ, which doesn't allow for a truly independent cross-validation. My rather obvious point was not that fit statistics should not be included (as Jones asserts) but that MJ included no errors in either input realization (observations or proxy data) or other obvious sources of error. The claim by MBH and MJ is that only the model lack-of-fit contributes to uncertainty is inherently flawed.

Considerable errors exist in the representation of both fields - annual temperatures from both observations and proxy records - and must be incorporated. Clearly, there is a spatial bias associated with observations that are biased away from the oceans, high latitudes, and high altitudes. The spatial problem is far more pronounced when only a handful of proxies are used to represent the global temperatures at earlier time periods. Both MBH and MJ are equally guilty in this regard.

Janice,

Most of the data series in most of the plots have just appeared on the CRU web site. Go to data then to paleoclimate. Did this to stop getting hassled by the skeptics for the data series. Mike Mann refuses to talk to these people and I can understand why. They are just trying to find if we've done anything wrong. I sent one of them loads of series and he barely said a thankyou. It seems they are now going for Tom Crowley, Lonnie Thompson and Gordon Jacoby as most of their series are not on web sites.

Below is a link to an awful piece by Legates. He told me he is a writing a paper, but wrote the press release first ! The pdf is worth getting for a couple of sentences, when he said that MJ restricted their use of paleo series to those that had correlations with instrumental data ! It is a classic. 'Our uncertainty estimates are based solely on how well the proxy records match the observed data' !

The Legates piece must have been sent to loads of environment correspondents across the world and a number of op-ed pieces appeared. Some were awful. Most have had responses from Ray Bradley, Caspar Amman and others.

Hope all is well with you and all the best to all. Glad you enjoyed the paper.

Cheers

Phil

PS Do you want to get involved in IPCC this time? I'm the CLA of the atmospheric obs. chapter with Kevin Trenberth and we'll be looking for Contributing Authors to help the Lead Authors we have. Paleo is in a different section this time led by Peck and Eystein Janssen. Keith is a lead author as well.

Phil Jones has made a valid point in that some of the articles cited in my critique do not 'directly' address problems with Mann and Jones (MJ) but rather, address problems with earlier works by Mann, Bradley, and Hughes (MBH) and other colleagues. Fair enough - I have changed the critique to reflect that fact. The revised version has been posted since July 19 at:

[1]<http://www.ncpa.org/pub/ba/ba478/ba478.pdf>

However, I still contend that most of my original arguments - namely, the problems with the shaft, blade, and sheath - apply equally to Mann and Jones as well as the other Mann et al. manifestations of the 'hockey stick'.

MJ incorporate data from a number of the same sources as those used by MBH; for example, Mann's unpublished PC1 from the western North

American tree-ring data, Cook's Tasmanian tree rings, Thompson's Quelccaya and Dunde ice core oxygen isotope records (the latter embedded in Yang's Chinese composite), and Fisher's stacked Greenland ice core oxygen isotope record. Calibration and verification of MJ includes the flawed MBH curve. Thus, any errors in MBH effectively undermine the calibration-verification results of MJ, leaving this study unsupported and any problems with the underlying common proxies identified in critiques of MBH will also result in identical problems in MJ.

My criticism regarding the blade is that 0.6 deg C warming for the last century is noted by the IPCC whereas MJ (and other M et al representations) have up to 0.95 deg C warming in their observed record. See MJ's figure 2 where for the global and NH reconstruction, their estimates for 2000 exceed +0.4 and +0.5 (nearly +0.6), respectively. MJ's NH curve is included in the attached graph. Thus, I stand by my criticism of MJ on this point, which is more egregious in MJ than other M et al representations.

>From Jones: "The trend over the 20th century in the Figure and in the instrumental data. IPCC quotes 0.6 deg C over the 1901-2000 period. Fact - but Legates is eyeballing the curve to get 0.95 deg C. A figure isn't given in Mann and Jones (2003). Take it from me the trend is about the same as the instrumental record."

Funny, but there IS a figure in MJ - see their Figure 2. As for me 'eyeballing' an apparently non-existent curve, I attach a figure from Soon et al. (2004) that contains a portion of MJ's Figure 2 to allow others to decide for themselves whether MJ suggest a twentieth century warming of 0.6 deg C or 0.95 deg C. Moreover, maybe someone can explain why every time Mann and his colleagues draft another curve, the temperature in 2000 gets warmer and warmer after the fact...

My criticisms regarding the sheath (largely from a paper on which I am working) stem from the characterization of the uncertainty by MJ that arises solely from the 'fit' statistics to the 1600-1855 period using cross-validation with, not observations, but composites of three previously compiled reconstructions, including that developed by MBH - the focus of known flaws and errors in the shaft. Note that some of the same data are used in both MBH and MJ, which doesn't allow for a truly independent cross-validation. My rather obvious point was not that fit statistics should not be included (as Jones asserts) but that MJ included no errors in either input realization (observations or proxy data) or other obvious sources of error. The claim by MBH and MJ is that only the model lack-of-fit contributes to uncertainty is inherently flawed.

Considerable errors exist in the representation of both fields - annual temperatures from both observations and proxy records - and must be incorporated. Clearly, there is a spatial bias associated with

observations that are biased away from the oceans, high latitudes, and high altitudes. The spatial problem is far more pronounced when only a handful of proxies are used to represent the global temperatures at earlier time periods. Both MBH and MJ are equally guilty in this regard.

Gabi,

No second attempt - don't know what the first was? We'll be doing a new instrumental data

set (surprisingly called HadCRUT3), but that's it at the moment.

Attached is a good review of corals - just out.

Cheers

Phil

At 10:36 10/08/2004 -0400, Gabi Hegerl wrote:

Hi Mike and Phil,

Thanks! Yes, factor 1.29 will get me closer to my best guess scaling (factor 1.6 to same-size signals).

The scaling is a tough issue, and I think there are lots of possibilities to do it depending on what one wants

to do. For comparing underlying forced signals, I think t1s is best. To get a conservative size paleo reconstruction

(like what part of instrumental do we reconstruct with paleo), the traditional scaling is best.

I'll write up what Myles and I have been thinking and send it.

Phil, if there is a second attempt at that with the Hadley Centre, let me know, I don't like racing anybody!

Gabi

Michael E. Mann wrote:

Dear Phil and Gabi,

I've attached a cleaned-up and commented version of the matlab code that I wrote for doing the Mann and Jones (2003) composites. I did this knowing that Phil and I are likely to have to respond to more crap criticisms from the idiots in the near future, so best to clean up the code and provide to some of my close colleagues in case they want to test it, etc. Please feel free to use this code for your own internal purposes, but don't pass it along where it may get into the hands of the wrong people.

In the process of trying to clean it up, I realized I had something a bit odd, not necessarily wrong, but it makes a small difference. It seems that I used the 'long' NH instrumental series back to 1753 that we calculated in the following paper:

* Mann, M.E., Rutherford, S., Bradley, R.S., Hughes, M.K., Keimig, F.T., [1]Optimal Surface Temperature Reconstructions using Terrestrial Borehole Data, Journal of Geophysical Research, 108 (D7), 4203, doi: 10.1029/2002JD002532, 2003.

(based on the sparse available long instrumental records) to set the scale for the decadal standard deviation of the proxy composite. Not sure why I used this, rather than using the CRU NH record back to 1856 for this purpose. It looks like I had two similarly named series floating around in the code, and used perhaps the less preferable one for setting the scale.

Turns it, this has the net effect of decreasing the amplitude of the NH reconstruction by a factor of $0.11/0.14 = 1.29$.

This may explain part of what perplexed Gabi when she was comparing w/ the instrumental series. I've attached the version of the reconstruction where the NH is scaled by the CRU NH record instead, as well as the Matlab code which you're welcome to try to use yourself and play around with. Basically, this increases the amplitude of the reconstruction everywhere by the factor 1.29. Perhaps this is more in line w/ what Gabi was estimating (Gabi?)

Anyway, doesn't make a major difference, but you might want to take this into account in any further use of the Mann and Jones series...

Phil: is this worth a followup note to GRL, w/ a link to the Matlab code?

Mike

p.s. Gabi: when do you and Tom plan to publish your NH reconstruction that now goes back about 1500 years or so? It would be nice to have more independent reconstructions published in the near future! Maybe I missed this? Thanks...

Mike,

I'd rather you didn't. I think it should be sufficient to forward the para from Andrew Conrie's

email that says the paper has been rejected by all 3 reviewers. You can say that the paper was an extended and updated version of that which appeared in CR.

Obviously, under no circumstances should any of this get back to Pielke.

Cheers

Phil

At 08:11 13/08/2004 -0400, you wrote:

Thanks a bunch Phil,

Along lines as my other email, would it be (?) for me to forward this to the chair of our committee confidentially, and for his internal purposes only, to help bolster the case against MM??

let me know...

thanks,

mike

Dear Phil,

IJOC040512 "A Socioeconomic Fingerprint on the Spatial Distribution of Surface Air Temperature Trends"

Authors: RR McKittrick & PJ Michaels

Target review date: July 5, 2004

Following from our email, many thanks for agreeing to review the paper above that has been submitted to the International Journal of Climatology for consideration. I have attached the manuscript, and the information for reviewers is provided below. Please let me know that you received the file.

In the interests of expediting the review process, I encourage you to email your review as soon as is convenient. I would like to hear from you by the target date above, or as soon after as possible.

Referee's names are kept anonymous. When composing your review, please keep your "Comments to the Author" separate from your confidential comments to the editor. With your comments to me, please be sure to provide one of these summary recommendations:

1. Accept without further revision.
2. Accept subject to minor revisions (changes to the text only, or simple follow-on analyses).
3. Accept subject to major revisions (major text changes, recalculations or new analyses).
4. Reject.

In the case of minor revisions, the revised manuscript will be checked only by the editor. For major revisions, the revised manuscript may be sent to you again for a second review. It will also be useful if you will grade the contribution overall on the following scale:

- A. Very good (a continuing and useful advance in an area of importance).
- B. Good (satisfactory and of sufficient importance to merit publication).
- C. Adequate (of marginal interest).
- D. Poor (not significant enough to merit publication).
- E. Very poor (trivial, or incorrect, or of no interest, or not new, etc.).

For your review, please also comment if any of the following points are not satisfactory or suitable: topic appropriate for the journal, correctness of the title, reduction in paper length, quality and quantity of illustrations, units, use of English, and key words.

Your contribution to the review process is essential and greatly valued.

Sincerely,

Andrew Comrie

Esper <esper@wsl.ch>, brazdil@sci.muni.cz, benito@ccma.csis.es

Dear Colleagues,

This note is to solicit your possible collaboration in an application to the European

Commission under Framework 6, possibly as one of the partners in IMPRINT. This is an

integrated palaeoclimate/climate modelling project concerned primarily with the Holocene,

but also incorporating specific studies on other interglacial warm periods. AT THIS STAGE

THIS IS A PROVISIONAL ENQUIRY RATHER THAN A DEFINITE REQUEST FOR YOUR INVOLVEMENT.

The project has been some time (years) in gestation and has evolved from other proposals.

An unfinished draft is appended to this message for your information - but we would ask

that you respect its confidentiality, whether or not you are interested in working with

us. Eystein Jansen has agreed to coordinate IMPRINT. We are now refining the initial

submission. I, and Valerie Masson, are nominally fronting WorkPackage 1: concerned with

assembling, reinterpreting, amalgamating and analysing the climate data; a combination of

instrumental, documentary and other indirect, proxy climate information. This Workpackage

will also organise the aggregation of best possible climate forcing proxy evidence, as

means of exploring links with the empirical climate data, but also as input to the

significant effort in climate modelling to be undertaken in other workpackages.

WorkPackage 1 has been divided into a number of sub themes or Tasks and these, along with

the content of all Workpackages, is described in the attached document. Note that this is

very much work in progress at this stage and your comments and input to all parts will be

welcome. We will refine the wider list of collaborating institutes at a later stage.

At this stage we envisage a total budget application of about 17 million Euro with a nominal share of 5 million for WorkPackage 1. While this is a large sum, I am sure you will appreciate that when distributed among many partners and stretched over five years it imposes a severe limitation on the total number of partners that can be feasibly included. Therefore we have had to conceive of different degrees, or levels, of involvement of the very many colleagues and institutions that are required to make this project a success. Thus, we envisage a distinction between a number of full partners, though again with varying resource allocation depending on specific inputs and requirements (still to be determined), and a larger number of collaborators. Specific funding will be allocated to facilitate the involvement of these many other groups, who we see taking part in workshops, in return for full access to joint data and modelling results. This is the only way that we see of overcoming the envisaged restriction imposed by the EC on total partner numbers.

We have chosen partners who we hope will be able to furnish expertise in specific research areas and, hopefully, facilitate data assembly and exchange between members of the wider communities.

PLEASE NOTE THAT THOSE PEOPLE LISTED IN THE "TO" LINE OF ADDRESSES ARE THOSE TENTATIVELY EARMARKED TO BE TASK LEADERS WITHIN WORKPACKAGE 1. THOSE LISTED UNDER THE "CC" HEADING ARE EARMARKED TO be PARTNERS - ORGANISING WORK AND DATA EXCHANGE WITHIN THEIR COMMUNITY. We

have a suggested list of many others who we would hope to involve - but not at full partner level. Your input to the completion of this list will be asked for later. We would ask that, for now, you do not circulate this provisional proposal. We realise that many other partners could have been fully justifiably included, but the need for pragmatism must eventually limit their formal roles. We hope that this reality will be accepted by those colleagues not included as primary partners and they will still be willing to collaborate to achieve the wider aims of IMPRINT.

The specific partner roles, as suggested to date, are described in the Workpackage 1

section of the appended IMPRINT document. Would you now please indicate whether or not you are willing to join this effort, and please feel free to comment on any aspect: of Workpackage 1 to myself and Valerie; or of the project as a whole to Eystein.

With very best wishes,

Keith

Phil

At 15:51 13/08/2004 -0600, Susan Solomon wrote:

Dear Phil, dear Kevin,

Thanks for your message. It's very good to hear that you are getting together and will have time to talk about this. I will make a few points and suggestions below for your consideration.

Safe travels,

Susan

Martin, Susan et al,

Kevin and I will be at a GCOS meeting Mon-Weds next week in Geneva, so will have some

time to discuss our chapter. I've sent Kevin some thoughts about boundaries between

chapters. If you can provide your views on a few issues, then it will help us in our discussions.

1. We have extended outlines, which clarify some issues, but how rigid are they? I say this

wrt the overviews/visions you expect on the Monday pm of the Trieste meeting.

The extended outlines show you what the thought process was at Marrakech and Potsdam that led to the present outlines. It's your report, and you may wish to do things differently. Where that may involve other chapters, such work would need to be coordinated/decided jointly but most things are not like that.

2. In Chapter 3, we have a section 3.9 on synthesis/consistency amongst obs. Does this

involve obs such as glacier retreat and changes in sea ice, snow cover from chapters

4-6? Chapters 4-6 don't have similar sections.

We had some discussions on that in Potsdam in particular if I recall. Dividing up the observations into three chapters solves some problems and raises others, and this is one

of them. My own thinking has been that issues such as the consistency of glacier retreat with observations may be better handled in the ice chapter, which presumably will be going into a bit more depth on processes affecting glaciers from the ice physics point of view, providing a bit deeper basis for the assessment. The consistency of observations between the three observations chapters could then be dealt with in the technical summary, drawing on the findings from all three. But it is probably going to be helpful if we have a discussion on this among the three chapters and come to a common view.

3. Chapter 1 has a section on new data and data rescue. I guess we should be involved in that, but also Ch 9 on attribution as it has to be worthwhile. Also the new data and rescued data could be useful for model validation. I expect Ch 3 to heavily use Reanalysis-based results.

Yes, we expected there would need to be discussion on that. It may involve a subset of people who should be urged to get together as needed.

4. Chapter 3 has SST and all the circulation indices, so here we need to liaise with Ch 5 and 6 and eventually with 9.

Yes, agreed, and Kevin and others tried to work that into the outline in Potsdam.

5. I agree with Kevin though on whether formal meetings of the whole of the chapters are needed. Might this be better done with the CLAs and you?

There will be a lot to do in Trieste and we want to make efficient use of people's time - it is probably true that not all the people need to be involved when the points you've made so far are discussed. The morning 1-hour sessions with all CLAs are also intended to be a forum where some of these kinds of issues (the broader ones) could be handled.

6. Considering all the above, I reckon we need to meet with Ch 4 and 6 (on glacier retreat, snow, sea ice and temperature), Chapters 6 and 9 on what they expect from us and similarly with Chapter 5 (although I feel this is clear in the extended outline). Finally, Chapters 1, 3 and 6 (and maybe 9) need to discuss data rescue and new techniques.

That sounds right to me. I would add your number 7 below into that mix as well.

It's really up to you to decide how you want to handle it. But prompted by your message, the one from Kevin below, and some others, I think it will be helpful for us to compile a list of all such issues raised - so I am asking the TSU to do that, combining with another set that we received in the comments from governments (they actually raised a number of such comments, quite rightly).

7. The Appendices in Chapters 3-5 need some sort of co-ordination.

Bests,  
Susan

At 11:31 11/08/2004 -0600, Kevin Trenberth wrote:

Martin, Susan et al:

In thinking more about Chapter 3, I believe we will have issues on who and what is covered on

- 1) ENSO related stuff Chapter 3 vs Chapter 5
- 2) Consistency of retreat of glaciers, snow and ice vs temperatures Chapter 3 vs chapter 4.

There are probably others, but these may require some negotiation unless it is already settled in your mind? Whether a formal meeting between chapters is needed or whether the CLAs can meet and agree is not yet clear to me.

Subject: Yamal treeline figures

Dear Keith,

Stepan Shiyatov tell me that you need some figures concerning Yamal chronology and tree line dynamics to show somewhere in France.

Attached are archived files contained some figures.

File MAP - the map of region of research. Red dots - subfossil wood sites, green marks - recent northern border of larch along river valleys.

File FIGURES - in Excel format, contains several figures.

Sheet "Values-10" - data on northernmost position of trees and number of trees dated for corresponding year (decadal step)

Sheet "Treeline" - dynamics of treeline in Yamal during last 7000 years reconstructed using about 1000 subfossil wood remains. Recent treeline position is about 67°34.

One year ago we supposed (C-14 data, Hantemirov, Shiyatov 1999) that significant drop of treeline (the transition from "middle" to "late" Holocene) was about 1700-1600 AD. According new data it was earlier (about 2550 BC). May be it is because of lack of data from region northward of 68°N (only 25 datings)?

Sheet "Treeline and Nu" - treeline dynamics and number of dated trees. May be number of trees reflects the long scale climate fluctuations as well.

Sheet "2600-all" - for last 4600 years: treeline dynamics, number of trees, 11 most cold summers for last 7000 years (according our version of reconstruction), most expressed frosts in July (reconstructed using junipers from Polar Urals, see file PATHOL, frost in 1626 BC - based on subfossil larch -

you can put away it), summer temperatures reconstruction smoothed with 20- and 100-year filters (our version of reconstruction).

Sheet "Values-2" - values for preceding figures, in 2-years step.

Sheet "Yam-Ur-fig" - comparing of treeline data for Yamal and Polar Urals upper treeline dynamics (data by S.G.Shiyatov)

Sheet "Yamal-Ural" - values for preceding figure, in 2-years step.

Sheet "Treeline-std" - treeline dynamics and 50-year standard deviations of summer temperatures (our version of reconstruction). This figure shows surprising high negative correlation. However may be both of them just reflect long scale climate fluctuations?

Sheet "Std" - 50-year standard deviations of summer temperatures (our version of reconstruction) .

File PATHOL - in Excel format, contains data and figure on pathological structures in tree rings of Siberian juniper (*Juniperus sibirica* Burgsd.). According our data (Hantemirov et al., 2000) the presence of frost rings provides evidence for frosts that occurred in late June or first days of July (frost rings in earlywood) and in the first half of July (frost rings in late wood). Long term and pronounced temperature drop in the middle of very warm period in the second half of July is the factor responsible for wood density fluctuations (false rings).

Please let me know when you receive this. Some time large messages get lost.

P.S. We (Eugene Vaganov, Stepan Shiyatov, Leonid Agafonov and I) will be in Birmensdorf from 23 till 29 October. Are you going to Switzerland after your meeting? We would be happy to see you there.

To: ITRDBFOR@LISTSERV.ARIZONA.EDU
Subject: Calibration loose ends (was Re: [ITRDBFOR] crossdating)
Date: Sun, 29 Aug 2004 11:46:03 -0700
Reply-to: grissino@UTKUX.UTCC.UTK.EDU

This an attempt to tie up the loose ends from an earlier part of the discussion, the idea that calibration of the radiocarbon timescale be considered invalid, pending a better understanding of crossdating. Some of the previous posts seem to imply that measurements of the C-14 half-life depend on the calibration; in fact it can be determined by present-day laboratory measurements without reference to any old material, simply by observing the decay rate in a known quantity of the isotope. Physicists seem happy that beta decay isn't affected by mundane external influences, so the half life should be constant. If the amount of C-14 in a sample depends only on its age and the (constant) half life, a calibration curve from a collection of samples of known true age would be a diagonal straight line; but this would imply that each sample started with the same concentration of C-14. There are many effects that could change this concentration through time: variations in cosmic ray sources, changing solar activity, changes in the upper atmosphere, atmospheric circulation, uptake and release of carbon from large sinks and sources... etc. Given enough correctly dated samples, you can recover the sum of these variations from the form of the calibration curve. In practice, the most important variation appear to be on multi-millennial scales, with smaller fluctuations (wiggles) on century/multi-decadal scales superimposed on this.

Wood from crossdated tree rings provided the known-age reference material used in the calibration curves, and there were two main phases of work, the first of which roughed out the general form of the curve and hinted at the short-period structure, the second of which reconstructed the century-scale variations in detail using higher precision measurements. Contamination of old samples with C-14 of more recent origin is a widely recognized problem, addressed by physical and chemical pre-treatment protocols for the material. A couple of complicating effects that are of more interest from a tree-physiological point of view. Isotopic fractionation occurs along the entire chain of processes between carbon in the environment and its incorporation in the specific components of the wood that end up in the calibration samples. A ring forming in a particular year might

continue to accumulate C-14 in subsequent years. But people who work with C-14 are well aware of various corrections for isotopic fractionation, and the migration of carbon across ring boundaries has been the subject of several empirical investigations, notably using the stepwise change in C-14 concentrations following atmospheric nuclear tests in the 1950s and 60s as a tracer. The more recent phase of calibration work was substantially complete around 15 years ago, and was covered in an extensive series of journal articles and symposia.

Let's suppose we have been provided with a demonstration that crossdating is invalid: what would be the consequences for C-14 calibration? One of the most alarming would be that we would have to come up with a convincing explanation of how independent tree ring chronologies could be in error in precisely the same way---the known-age reference samples are not just from bristlecone pines, and crossdating within the network of oak chronologies is completely independent of the bristlecones. Both are completely self-supporting chains of inferences anchored in living trees and extending back into sub-fossil wood. There are published comparisons of paired calibration curves, with the absolute dates and C-14 concentrations based on oaks in one case, and on bristlecones in the other. My understanding of tree physiology is rudimentary at best, but surely when two such vastly different wood anatomies are involved there must be differences in the physiological constraints on wood formation. If potentially unidentified missing rings are supposed to be the most serious problem with the bristlecone chronologies, the oak chronologies should not be affected in any case, since they almost never include missing rings in this sense (although that's not to say they have no anatomical ambiguities that can confound crossdating). The crossdating error could not be merely a shared systematic bias; not only does the long term trend in the calibration curves derived from the two chronologies share a common non-linear trend, but the short-term fluctuations in C-14 concentration (wiggles) match between the two curves. There are small differences between calibrations derived from different geographical regions, but these have themselves formed the basis for further research and geophysical modeling.

The strengths of the two sets of chronologies are complimentary. Oaks may have almost no missing rings (*sensu stricto*) and provide larger volumes of wood for C-14 analysis, but the individual samples are only a few hundred years long, showing significant variations in growth with increasing pith age, and (particularly in the case of the

sub-fossil wood) there will be uncertainties about the environment in which the tree was growing. Bristlecone pines give a much better chance of finding wood that has grown over periods of many centuries with no marked age-related trends, and there's a compelling continuity between the living trees and the remnant wood lying on the ground nearby.

An account of wood formation from a physiological perspective would undoubtedly be a beautiful thing in its own right, even if it had little to contribute to dendrochronology. Moreover one of my pet peeves is seeing people manipulate data as mere collections of numbers divorced from any underlying model---and in the case of dendrochronology the model has to be biological. But I'd number myself amongst those who can't see why our use of crossdating must await a reasonably complete physiological model of wood formation. By analogy, if the doctors in some traditional society are using a human physiology based on the balance or imbalance of the four humours, but they have a treatment for a particular disease that results in an 80% survival rate, as opposed to a %40 survival rate if it goes untreated, you're obviously better off slurping down their bitter potion first and working out the explanation in current Western physiological terms afterwards (if that's the only treatment option).

So even if at present our understanding of crossdating is largely limited to statistical phenomenology, that may be good enough to live with until something better comes along. That's not to imply that we should be credulous, and automatically accept current practices simply because great authorities have taken the same route: astronomers were at one time expected to work as astrological consultants, casting horoscopes for rulers and interpreting signs in the sky in terms of current political affairs. There's no necessary reason to follow Douglass' crossdating methods any more than we should follow Kepler's example of casting horoscopes---unless they work. Although the seeming effectiveness of crossdating could in principle be invalid, it has been applied so widely that we would need presented with a very strong critique before abandoning it.

I'm not really qualified to discuss crossdating and C-14 calibration from a point of view of someone active in current research, but was fortunate to be sitting on the sidelines of the oak calibration work in the 80s, and just the other day Tom Harlan dropped by with the oldest known absolutely dated bristlecone sample, so will offer this as a kind of correction by proxy until any of the people

who've done the real work care to comment

---Martin.

Tom,

Ben should have seen the ERA-40 Report # 18. You can forward the JGR paper.

WRT 1, it is difficult to say as it depends who's produced the values. For HadCRUT2v, I think I've convinced the HC that the globe is $(NH+SH)/2$. If Peter Thorne did the calculations then this will be the case.

There is another issue. Sometimes the trends over Jan79-Dec03 are calculated from the 300 months rather than the 25 years. Christy does this, I think.

NCDC's Globe is probably the one domain. I've been doing some work with Russ Vose at NCDC, which he's still to write up. Most of the differences were due to how the globe was calculated. It is more informative to also include NH and SH as well as globe in such tables. I'll forward a plot Tom Peterson produced a week or two ago.

ERA-40 (2)comparisons are discussed in the ERA-40 report # 18 and the JGR submitted paper.

This also has comparisons by continent, which again are more informative. There is a plot in that work from the full globe vs the CRU coverage. I wouldn't believe their tropics.

Also

Antarctica is way off as well - at least where the surface data are located, so I wouldn't have much faith in their values for the unmonitored parts.

On (3) I did some comparisons ages ago with Jim Angell's surface data from sondes. Jim's data was just noisier and I suspect LKS would be also. I've not done anything like this for

ages. The closest would be the ERA-40 comparisons, which is much more extensive than the LKS network.

I might have a chance to do an LKS comparison if Dian sends me the co-ordinates.

Comparisons over 1958-2003 will be much more realistic, but the ERA-40/NCEP degrade prior to the 1960s. LKS would be better here. All sonde data look odd in the late 1950s to the early 1960s. The jump around 1976/77 has always intrigued me. It is bigger in some regions than others - I think it gets more credence because it is large over western North America. Kevin had a paper on this in BAMS in the late 1980s.

Cheers

Phil

Phil,

On Sept. 13-17 I will be at a meeting at the Met Office to do with a report we are writing on trends in vert temp profiles as part of the US Climate Change Science Program (CCSP). It involves all the usual suspects. Seven chapters, the last of which is equivalent to a summary for policy-makers -- for which I am the lead author. Various people are updating data sets and doing calculations of trends, etc. Some of the surface numbers I found to be a bit disturbing -- so I am asking for your opinion. These are trends per decade for Jan. 1979 thru Dec. 2003

| SOURCE | GLOBE | 30S-30N |
|-----------|-------|---------|
| HadCRUT2v | 0.169 | 0.127 |
| NCDC | 0.151 | 0.146 |
| ERA40 | 0.113 | 0.032 |
| LKS | 0.074 | 0.056 |

(1) CRU and NCDC are consistent within the noise, but I have one question -- how do both calculate GLOBE?

(2) ERA40 is marginally OK (relative to CRU) in GLOBE, but the tropics is alarmingly different. (The diff here accounts for the GLOBE difference.) Why is this? Which is better? Is this discussed in your paper with Adrian?

(3) LKS is the surface data from the corrected LKS radiosonde data set. The difference here must be partly due to coverage issues. But I recall that years ago we saw a difference between surface sonde and CRU data. Have you done a like with like comparison (i.e., selecting the LKS sonde sites and extracting the corresp CRU (and NCDC, and ERA40 -- and (if possible) NCEP) data? This seems to be a pretty basic sanity check on the sonde data -- so, if you have not done this already, could you do it for me please?

I think there is a nice little GRL paper here. For the CCSP we are also giving trends, etc. over 1958-2003. So the real need is for a full time series comparison over this period -- i.e., not just trends. In other words, what I would like you to produce is the monthly time series for the various data sets for the LKS coverage. If you don't know the LKS site locations, I can get these for you.

Re going back to 1958, the sonde trop data have a well known (but not well explained) problem over roughly 1958 to 1964/5. I am curious as to whether this shows up in the LKS surface record. I am also curious about the apparent 1976 jump -- some people have made a lot of noise about this, but I don't see it as a major item in the global surface data. So the Q here is, is is apparent in the restricted coverage of the sonde data?

I hope you can help. I am leaving here on Sept 7 to spend a few days with a friend of mine in Plymouth -- you could contact me thru him (I

am copying this to him so you can see his email).

Thanx,

Tom.

Tom,
Program and the input LKS file. Program is adapted from one I had. Ended up a little convoluted. Should work with any of the 4 CRU temp data files (CRUTEM2(v), HadCRUT2(v)). For the Russian, grid point, changing 4 59 to 4 57 will give a box with data in from 1929.
3rd file is my unix run file - for files to channels.

Cheers
Phil

Tom,
Here are some files to look at and think about. John Lanzante has sent me the locations of the 87 stations in the LKS dataset. I associated these with CRU 5 deg grid boxes and calculated NH (based on 54 sites), SH (32) and Global (as one domain), so to get the globe the CRU way you need to average the NH and SH series (all to 3 deg places). The second line in all the results files is the count of stations. I can do this as % area if you want.

The CRU data I used is the file hadcrut2v, so this includes SST anomns over the

ocean.

I can repeat this with the land only file. Used the variance corrected version.

There are 4 files

1. The LKS stations. This is what John sent with the lat/long identifiers for the grid boxes on the front.

2-4 NH, SH and Globe as one domain results.

The first file has a fix in it. This is to pick up the 5 deg square (85-90S, 5W-0) that has

the South Pole data. This square is where I've always put this data.

For the NH there were 54 sites and for the SH 32. Site 9 (WMO ID 21504) is always missing,

even with hadcrut2v. The site is located on an island in the Laptev Sea. There isn't a surface

site anywhere near it. I could move the location and pick up the nearest CRU box, but it will

be over 5 deg of lat and 10 deg of long away. It's somewhat unusual for sonde sites not to have

a surface site near them. I guess it just doesn't report its surface data.

I'm here until Sept 15 then away for much of the time until end of October. I could send you

the program, which should run with crutem2v or the non-variance adjusted versions, which you

could pick up from the CRU web site.

Cheers

that is a useful way to look at it.

again, takeaway msg is that mann method can only work if past variability same as variability during period used to calibrate your method.

so it could be correct, but could be very wrong as well.

by the way, von storch doesn't concur with osborn/briffa on the idea that higher past variability would mean there'd likley be high future variability as well (bigger response to ghg forcing).

he simply says it's time to toss hockeystick and start again, doesn't take it further than that.

is that right?

Date: Fri, 01 Oct 2004 11:49:05 +0200
Reply-to: stefan@pik-potsdam.de
Cc: wg1-ar4-ch06@joss.ucar.edu

Hi co-authors,

here are some thoughts on what to say on climate sensitivity in our chapter - this is an attempt to focus on the main, simple messages for policy makers. (I think we should try retaining those important messages and not lose sight of them amidst all the details, complexity and caveats.)

The main policy-relevant question could be phrased as follows: Does the past climate history tell us how sensitive the climate system is to CO₂?

I submit that the answers to this we get from different time periods are the following.

Deep Time:

Reconstructions are too uncertain (and boundary conditions too different, e.g. continents in different places, different ocean circulation) to draw quantitative conclusions about sensitivity to CO₂, but there is clear evidence that times of high CO₂ in Earth history tend to be ice free (Royer et al. 2004). A second piece of evidence is the Late Paleocene Thermal Maximum, which shows that the climate has responded by warming to a large carbon release into the atmosphere. Just how large this carbon release was is not known, since several origins of the carbon are possible, which have different isotope signature and would thus imply different amounts. But the temperature response was large (6K), and if anything this response would point to a high sensitivity.

Glacial-Interglacial Changes:

We have by now sufficiently good quantitative reconstructions of CO₂ and other forcings as well as temperatures in order to derive useful quantitative estimates of climate sensitivity. LGM was the most recent time in history in which CO₂ concentration differed greatly from pre-industrial values, by as much as it does now. It is the closest test case for response to CO₂ changes that we have.

There are two basic methods to derive climate sensitivity:

(i) Based on data analysis - e.g. Lorius et al. 1991 (concluding sensitivity is 3-4 K).

This method has the caveat that this sensitivity applies to colder climate, which may differ somewhat from that which applies in present climate as the strength of feedbacks is expected to depend on the mean climate (e.g., stronger snow-albedo feedback in colder conditions).

(ii) Based on combining data and models - e.g. Schneider von Deimling et al. 2004. Does not have the above caveat, but depends on models.

Lag of CO₂ behind temperature does not imply a lack of CO₂ effect on climate, since the lag is small (centuries, not millennia).

Holocene, last millennium

??

Overall conclusions

Qualitatively, climate history is at least consistent with the accepted CO2 sensitivity. There is no evidence for much lower or much higher CO2 sensitivity (note that CO2 is not the only forcing). The more recent climate history (as far back as ice core data go) does allow quantitative inferences. The results of these estimates all lie within the IPCC range and provide strong support for this. Paleodata may even allow to reduce this range, since at least one study argues that values above 4K are very likely inconsistent with the reconstructed LGM climate: for high CO2 sensitivity, tropical cooling in the glacial should have been larger.

Cheers,
Stefan

WE SAY *NO* LOW FREQ FORCING. C-14/Be-10 ARE PROXIES FOR MAGNETIC FIELD
CHANGES. THERE
IS NO ADEQUATE THEORY RELATING THESE TO LUMINOSITY CHANGES -- IN FACT

THEORY SUGGESTS

THEY ARE *NOT* RELATED. SO WE ARE SUGGESTING A DIFFERENT FORCING HISTORY, WITH IMPLICATIONS AS IN THE FIGURE. NO SOLAR-INDUCED LIA, IN ACCORD WITH THE PROXY CLIMATE RECONSTRUXIONS. FURTHER, THERE IS SOME RECENT WORK SUGGESTING THAT PART OF THE C-14/Be-10 CHANGESW ARE DUE TOCHZNGES IN THE *EARTH'S* MAGNETIC FIELD.

Subject: Re: More vertical profile plots
Date: Thu Oct 7 10:28:36 2004

Ben,

Thanks for the plots. I gather from Karl that you'll be in Seattle and not at the HC review.

I'll be in Seattle also and am missing the HC review, so we can catch up on things.

Last week was the first LA meeting of AR4. You have likely been contacted by Kevin and also maybe by Brian Soden about writing something on tropopause heights. It would perhaps be useful to send them these figures and maybe also to David Parker.

For our chapter Kevin is co-ordinating the U/A and circulation sections. I'm doing the surface T/P and extremes and the final summary. I've been too busy to think about anything

yet ! We have a mix of abilities in the LAs, but Brian, David P, Dave Easterling and Albert

Klein Tank of KNMI are solid. The Iranian, Argentinian, Romanian, Kenyan don't seem up to too much, but this is life in the IPCC - remember Ebby !

The fact that HadCRUT2v is close to PCM may be fortuitous, but good nonetheless. If you

subsample PCM with CRU coverage, you say the PCM trend will reduce. The paper and report with Adrian shows that if you look at the full ERA-40 surface T data, then the reverse happens.

Not a large increase though. Most comes from the SH, so there are issues of what ERA-40 is doing over the Southern Oceans, Antarctica and Australia are key. I'll be talking about this

work in Seattle.

I don't have any IDAG work to give you - not done a lot. Plan to look at the 1740 event in Europe, when time permits. If you want any of my ppt for your IDAG talk, you can look through in Seattle.

Good to catch up in a weeks time. Hope you and Nick are well. Away next week in Delhi at a GCOS workshop.

Cheers

Phil

At 01:50 07/10/2004, you wrote:

Dear Jerry, Ram, and Jim,

Here are the profiles of zonally-averaged atmospheric temperature change that you requested. As I mentioned in yesterday's email, I've prepared a couple of different versions of these plots. First, there are two different analysis periods: January 1979 through to December 1999, and January 1958 through to

December 1999. Second, temperature changes are expressed in two different ways: in terms of linear trends per decade, and in terms of the total linear changes over the two analysis period. So there are four different vertical profile plots:

```
-rw-r--r-- 1 bsanter climate 194436 Oct 6 16:27 ccsp_vp_lt_1979-1999.ps
-rw-r--r-- 1 bsanter climate 142312 Oct 6 16:27 ccsp_vp_lt_1958-1999.ps
-rw-r--r-- 1 bsanter climate 201997 Oct 6 16:43 ccsp_vp_tlc_1958-1999.ps
-rw-r--r-- 1 bsanter climate 198109 Oct 6 17:04 ccsp_vp_tlc_1979-1999.ps
```

All the relevant information is encoded in the file name: "lt" denotes linear trend, and "tlc" denotes total linear change. Personally, I have a preference for the total linear change plots. If you compare panel f (the PCM ALL forcing case) of the "tlc" plots for 1979-1999 and 1958-1999, the much larger total changes over the longer analysis period are visually obvious. This is not the case if changes are expressed in degrees C/decade.

I note that (as requested by Roger Pielke in Exeter), the plots are appropriately area weighted.

All profiles of zonally-averaged atmospheric temperature change are ensemble means. Each ensemble mean was calculated from four individual realizations.

There is no subtraction of control run drift, which probably is not a significant factor at this point in the perturbation experiments.

I've also updated the two plots that I sent you yesterday, which show global-mean and tropical-mean profiles of atmospheric temperature change. These plots now include observed near-surface temperature trends, estimated from HadCRUT2 and HadCRUTv (the latter is the variance corrected version of HadCRUT2). PCM ALL and HadCRUT near-surface temperature changes are in good agreement, both for global- and tropical averages. I'm pretty sure that in the global-mean case, subsampling PCM ALL results with HadCRUT coverage would yield a slightly warmer PCM ALL 2m temperature trend (in view of the muted warming of 2m temperatures at high southern latitudes in ALL; these areas are not well sampled in HadCRUT).

It would be nice to show these plots of global- and tropical-average changes in Chapter 5. I think they make some useful points.

Hope all of this is helpful,

With best regards,

Ben

(P.S.: I'd like to acknowledge the assistance of Charles Doutriaux and Mike Wehner in producing these plots. Considerable data processing was involved in generating these six figures).

Hi Keith,

I can take a stab at the THC bit (not strong evidence so far for linkages to multidecadal/century scale changes, but cannot be ruled out) the marine evidence from the North Atlantic (14C chronological control), and some aspects of tropical/high latitude linkages.

Subject: Re: comment Von Storch?
Date: Thu Oct 14 16:29:31 2004

Mike,
FYI.

I met this guy in Utrecht last week at Albert Klein Tank's PhD ceremony. It appears from many media reports that people really believe that their run is an ALTERNATE to yours - based

on no proxy data. Even Hans has sent an email around to this effect, but he obviously isn't

making it as clear as I've just done to this Dutch journalist. I think he might be being clear with

fellow scientists and economical with the truth with journalists, i.e. not directing them down the

correct path when he sees them going down the wrong one.

I should see Ray next week in Seattle at a DoE meeting.

Cheers

Phil

Dear Karel,

I have only got back from a meeting this morning. I see you have also had a long reply from

Mike Mann about the von Storch paper.

Basically the von Storch et al paper is a discussion of the methodology used in the Mann,

Bradley Hughes papers from 1998, 1999. It doesn't contain any new nor any observed proxy data. It is entirely a model study. Therefore, it cannot produce a record for the last millennium,

it cannot claim that the Medieval Warm Period was warmer than today, nor that the Little Ice

Age may have been colder than MBH says.

It is really alarming that many media people (including yourself) have been taken in. What the

von Storch et al paper is about is a climate model run - just one simulation. All it uses is

an estimate of past variations in solar forcing and volcanic eruptions and more recently anthropogenic changes in greenhouse gases and sulphate aerosols.

As I said the paper in a methodological critique of MBH, nothing more than that. It IS NOT

an alternative to MBH. It also not based on ANY paleoclimatic data. If you believe it, you are putting everything on the model being correct and that their best guess at the past

history
of forcing as being correct.
Regards
Phil

At 15:28 13/10/2004, you wrote:

Dear professor Jones,
(We met ten days ago in Utrecht, when Albert Klein Tank got his PhD).
I am a science journalist of the Dutch daily newspaper NRC Handelsblad in Rotterdam ([1]www.nrc.nl).
I try to write an article about climate (surface temperature) reconstruction as far back as the year 1000 - the well know Mann, Bradley, Hughes (1998 and 1999) research. The reason is, of course, the publication of the article of Von Storch, Zorita, c.s. in Science-online (30 september). Von Storch claims that the statistical approach of Mann c.s. produced a serious underestimation of the low frequency (long term) oscillations in global temperature. The conclusion could be that the Medieval Warm Period was in fact warmer than today. And the recent warming is - after all - not so special.
Can you in a few words - and for a general public - give a comment on the paper? Does it make sense? It seems pretty convincing to me.
Can you help me?
Waiting for your reply,
sincerely yours,

Subject: IMPRINT Budget (Work package 1)
Date: Wed Oct 20 13:49:34 2004

Dear Partners in Workpackage 1 of IMPRINT,
today is the deadline by which Eystein requested input as regards the
reworked (and necessarily much shortened), proposal document. We have
also been making some
effort to consolidate the indicative budgets that most of you have
sent to us.

We now need to transfer these figures to Eystein , even though a few
partners have not
supplied numbers to us , though they may have sent them to Eystein
directly.

It is clear that we are now close to 30 partners in Workpackage 1
alone, and have
indicative budget requests totaling well over the nominal 5 million
Euro originally
allocated. In fact , the likely total with all partner requests
included is likely to be
nearer to 10 million!

We have been given a (very unofficial) hint from Brussels that an
"appropriate" total
project request of about 17 million for IMPRINT might be sensible ,
with a final figure ,
if the project ever gets accepted, of 15 million being possibly
awarded (subject of course
to referees' comments and subsequent reorganisation of priorities).
The simple message is that Eystein will now have to make an executive
decision as to the
total amount requested .

If we ever get that far, reorganised budgets will have to be decided
on the basis of very

specific
work plans that will need to be formalised for a second submission -
especially as they relate
to the justification for field work and new data analyses. We also
need to budget for the
involvement of non-partners , possibly using a mixture of workshop and
minor funding awards
to facilitate data collection etc.

It has been made clear that new practical work campaigns would not be
sanctioned across all

Tasks

in Workpackage 1 . Rather, the bulk of work would involve re-
dating/interpretation of
mostly existing data and reconstructions of forcings and climate .
Specific cases will have

to be made to justify sampling and processing of new data.

Thanks to all of you for your help and thanks to Eystein for taking on
the enormous task of

organising this proposal .

Keith and Tim

Hi Keith,

When would be a good time tomorrow (or next week) to phone you about the data you have available at your website from your QSR 2000 paper.

I am particularly interesting in using the long chronologies from the Polar Urals (Yamal) and Tornetrask.

This is for Gordon's and Rosanne's NH temp recon update, so I thought I should have a chat with you before using the data.

all the best

Rob

From: Phil Jones <p.jones@uea.ac.uk>
To: Tom Wigley <wigley@cgd.ucar.edu>
Subject: Re: MBH
Date: Fri Oct 22 15:13:20 2004
Cc: santer1@llnl.gov

Tom,

Just got the Science attachments for the von Storch et al. paper for Tim and Keith, so I thought you might like to see them. I've just sent a reply to von Storch as he claims his model is a better representation of reality than MBH. How a model that is only given past forcing histories can be better than some proxy data is beyond me, but Hans seems to believe this. The ERA-40 report and JGR paper are relevant here. ERA-40 is not of climate quality. There are differences and trends with CRU data before the late 1970s and again around the mid-1960s that should include other variables that are calculated. It is so bad in the Antarctic that ERA-40 rejects most of the surface obs (because they get little weight) and they don't begin to get accepted until the late 1970s. Conclusion is that

you can't consider ERA-40 for climate purposes. Maybe the next generation, with a considerable efforts in getting all the missing back data in and changes to weights given to surface data might mean the 3rd generation is better.

I shouldn't rabbit on about this as I have to go home to drive with Ruth to Gatwick for our week in Florence. A lot of people criticise MBH and other papers Mike has been involved in, but how many people read them fully - or just read bits like the attached. The attached is a complete distortion of the facts. M&M are completely wrong in virtually everything they say or do. I have sent them countless data series that were used in the Jones/Mann Reviews of Geophysics papers. I got scant thanks from them for doing this - only an email saying I had some of the data series wrong, associated with the wrong year/decade.

I wasted a few hours checking what I'd done and got no thanks for pointing their mistake out to them.

If you think M&M are correct and believable then go to this web site

[1]<http://cgi.cse.unsw.edu.au/~lambert/cgi-bin/blog/>

It will take a while to get around these web pages and you've got to be a bit of nerd and know

the jargon, but it lists all the mistakes McKittrick has made in various papers. I bet there isn't

a link to this on his web site. The final attachment is a comment on a truly awful paper by

McKittirck and Michaels. I can't find the original, but it's reference is in this. The paper didn't consider spatial autocorrelation at all. Fortunately a longer version of the paper did get rejected by IJC - it seems a few papers are rejected !

Point I'm trying to make is you cannot trust anything that M&M write. MBH is as good a way of putting all the data together as others. We get similar results in the work in the Holocene in 1998 (Jones et al) and so does Tom Crowley in a paper in 1999. Keith's reconstruction is strikingly similar in his paper from JGR in 2001. Mike's may have slightly less variability on decadal scales than the others (especially cf Esper et al), but he is using a lot more data than the others. I reckon they are all biased a little to the summer

and none are truly annual - I say all this in the Reviews of Geophysics paper !

Bottom line - there is no way the MWP (whenever it was) was as warm globally as the last 20 years. There is also no way a whole decade in the LIA period was more than 1 deg C on a global basis cooler than the 1961-90 mean. This is all gut feeling, no science, but years of experience of dealing with global scales and variability.

Must get to Florence now. Back in Nov 1.

Cheers
Phil

Adrian and Ben,

Roger Pielke did send this to me over the weekend, so he's being honest in one respect. I still think he's reading far too much into NCEP1. The bottom panel of their Fig1 shows both CRU and GHCN (-ERA40) having no difference over the period from the late 1960s. If the obs assimilated before 1967 (even in the US) were improved, the apparent drop before might disappear.

Cheers

Phil-

FYI; thank you for sharing your paper. I have circulated the attached to our CCSP Committee with the permission of Eugenia and Ming, and want to also share with you.

The conclusion from my own work with the NCEP reanalysis is that it is appropriate for trend assessments if integrated metrics are used (thickness for example), and for regions where the regional trend signal is quite large. We have published on both of this issues. One value-added of reanalyses is that since the winds are monitored independently of the temperatures, they provide information on the horizontal layer averaged temperatures in the mid- and high-latitudes, which helps adjust, to some extent, biases in the temperatures.

Also, as we have shown with regional data (e.g. Florida) and others have shown elsewhere (e.g. Andy Pitman for Australia) there is a clear land use change signal on surface temperature. This provides independent evidence that the Kalnay and Cai results should be expected.

Roger

Hi All

I requested to Ming Cai and Eugenia Kalnay that they respond to the comments regarding their work. The response is forwarded to you in this e-mail.

This debate, of course, should really take place in the literature. There has been, however, in my view an unfortunate change over time where reviewers who disagree with already published work recommend rejection of subsequent work rather than letting the community view and assess the different perspectives on a science issue. Our report has to make sure it is inclusive, in order to avoid this pitfall.

An unbiased discussion of the K&C results, and ways to resolve the disagreement through hypothesis testing, should be included in the appropriate chapters.

Roger

Subject: Re: K&C

Dear Roger,

Attached is the preliminary summary report on our recent work on the estimate of land-use-change climate impact using the reanalysis. Very fortunately, we had secured a one-year funding from NSF starting last August. Despite a short time period, we have already produced sufficient

results to confirm the robustness of our original work using different datasets that have the state-of-art quality.

Here I just want to add one more comment about Simmons et al. paper. Basically, they claimed that the difference between the ERA40 and CRU is very small and therefore, our method is not applicable if the reanalysis is as good as the ERA40. There are two things that are incorrect in their claims. First of all, if the reanalysis were made to be exactly the same as the observations, by definition, there would be no difference between reanalysis and the surface observations. Since the ERA40 was obtained by directly assimilating the CRU surface observations whereas the NNR didn't use any surface temp. observation, it is natural to expect that the difference between the surface observation and ERA40 is small. Second, Simmons et al. manually reduces the difference between the ERA40 and CRU by setting the mean difference between the ERA40 and CRU from 1987 to 2001 be ZERO. As a result, the difference "LOOKs" very small in recent years. However, the difference from 1961 to 1985 has to be larger (otherwise, they would make an error in their plot). In other words, by doing so, the gap between the ERA40 and CRU appears decreasing in time rather increasing in time as shown in KC and in the new figure 1 in the attached file (which is the same as Simmons et al. paper except we reset the 1960-70 to be zero in order to see how the POSITIVE gap increases in time). If we closely examine their figures, we will see by applying their treatment, the gap between CRU and reanalysis is a NEGATIVE one (e.g., CRU is below ERA40 from 1960 to 1980) and such a NEGATIVE gap decrease in time is equivalent to that the POSITIVE gap increases in time as found in KC from the NNR data (e.g., the CRU becomes more above the ERA40). So Simmons et al's results actually CONFIRM our findings rather discredit our finding. We actually reproduced Simmons et al calculations and confirm that their results are correct (see the second attached figure, which is identical to Fig.1 in our preliminary report except the NEGATIVE gap is used and 1-year running mean was applied as in Simmons et al). But their interpretations are incorrect.

I appreciate if you could also forward the email to the CCSP authors. Let me know if you want to me to reply to Tom and CCSP co-authors directly.

Regards.

Ming

The report:

The replica of one of the key figures in Simmons et al.

On Nov 18, 2004, at 4:53 PM, Roger Pielke wrote:

Tom-

Since we have not seen the paper, we cannot make any judgements on the robustness of that paper in showing that the Kalnay and Cai work is "flawed". I expect to have a summary by Eugenia and Ming tomorrow, however, which will address the published concerns on their work, and

will
forward to the Committee. Please forward us a copy of the Simmons et al
paper.

I also would like a response to my MWR Florida paper where we
specifically show the dominant role of documented land use change in
peninsular Florida in the 20th century on July-August surface air
temperature change. Or Andy Pitman's work who shows a major effect on
temperature trends in south-western Australia due to land use change.
This work, and others like it, support the conclusions of Kalnay and
Cai
on a major role of land surface processes on surface temperature
trends.

How do you reconcile those independent conclusions with the paper you
list above?

Roger

Folks,

Roger makes the point that there is no comprehensive assessment of
this

paper.

There is ... It is in a paper that has, I believe, been accepted by

JGR

atmospheres.

A.J. Simmons, P.D.Jones, et al. "Comparison of trends and
low-frequency

variability in CRU,

ERA-40 and NCEP/NCAR".

I think the conclusion is that the K&C paper *is* flawed.

Viv

attached is the text you sent with some suggestions and comments (track changes must be on).

I am also sending a small piece of text that could be expanded if needed (this to be inserted where you describe the tree-ring input) - but at this stage I think you need to have a look at comments and consider the specifics of the lake and tree sampling (the latter if any).

I thought it best to send these comments rather than plough on doing stuff you don't want. I think the "hook" needs to be the important opportunity to assess recent changes in lake and tree productivity and see if any evidence for response to climate, as well as searching for unprecedented evidence of climate change. I realise this is predominantly a lake project with a link to trees and models, but the links must be more than token. I can provide more background as to where we are with tree-ring work in Euro-Siberia if needed. I think the model stuff also needs specific justification. Is Simon going to contribute here?

Don't get hung up on the "decline or changing sensitivity issue" in trees. This is NOT a great problem in Scandinavia, Ural/Yamal and is anyway a divergence in trend and quite subtle and evident in wood density mostly. We are also of the opinion that it could be partly a statistical processing artifact - we are exploring this now.

If you plough through my comments and suggestions and then return the text with specific requests of what you wish to do I will then try to oblige Thursday

cheers

Martin

in response to Nadia's message and our talk - consider the following as regards title and objectives

Title

The precedence of Ecological Responses to 20th Century Climate changes in Arctic Lakes and Trees

Suggested Objectives

We will quantify how the changes in 20th century Arctic climate (including mean and variability) are reflected in recent and past lake sediment records. We will determine the response of lake ecosystem parameters and the relationships with specific climatic controls.

We will define the character of variability in different natural archives contained in dated sediments reaching back over 2000 years. We will generate well-calibrated, high-resolution (decadal to centennial time scales) estimates of past summer climate variability over this time in western Arctic Siberia.

We will compare the lake sediment data with evidence of tree-growth and associated summer climate changes, based on selected updating of an extensive, existing network of chronologies, including long sub-fossil series extending back more than 4000 years in Yamal and Taimyr. These data (with perfect inter-annual dating accuracy) will be reprocessed to provide summer temperatures specifically representative of annual, decadal and centennial timescales.

We will determine (for the first time) the extent to which the independent proxy-based summer climate histories concur or disagree and explore the extent to which they demonstrate the precedence of recent (20th century) climate trends in a multi-millennial context. By comparing this evidence with the output of state-of-the-art GCM experiments, simulating climate changes in the Arctic over the last 500 to 1000 years, we will explore the degree to which recent changes in Arctic lakes (and tree-growth rates) are attributable to anthropogenic as opposed to natural climate changes.

Dear Toms, Chris and Ben,

If large-scale is important (as said by Tom W), I can't see how microclimatic issues that Roger goes on about can be that important. Maybe when you all meet at the delightful Chicago Airport Hilton, you can remind him of spatial degrees of freedom.

Is the NOAA Tsurf used the new Smith and Reynolds (2005) spatially infilled surface dataset? If this is the case maybe Ben could do a plot of NOAA minus HadCRUT2v?

I have a plot that David Parker produced of Smith and Reynolds (2005) over land and Jones and Moberg (2003) land (as smoothed global averages) from 1880. Prior to about 1960 the SR dataset is always about 0.15 warmer than JM. This looks likely due to infilling with 61-90 averages (i.e zeroes) over the Antarctic and some continental interiors of S. America, Africa, western China and Australia (where there are no obs pre early 1950s, 1956 for the Antarctic). SR should be OK for 1979-99 and be very similar to HadCRUT2v.

Cheers

Phil

At 23:31 01/12/2004, Roger Pielke wrote:

Tom-

One issue to sort out with respect to "VTT" remains whether there are unrecognized biases in the surface data. This issue is very much relevant if, as seems the case from Phil Jones's e-mail, the "raw data" that has been used has such large overlap among the different surface analyses. If this is the case, there are not three independent assessments of surface temperature trends. Moreover, unlike the MSU data, there are inhomogeneities associated with the diverse locations of each surface monitoring site (which have microclimate changes over time).

This issue is also very much a tropical issue as this is where large land use/land cover change has occurred in the satellite era (photographs rather than written documentation would really help in this assessment, as we have proposed).

Phil

David,

I will send you this once we post the ZOD on the WG1 web site in mid-Jan05. Our diagrams are in a state of flux. Most of the temperature and precipitation trend maps are being done

in Asheville and I should be getting them later this week or early next. We will be showing maps

for the whole 20th century, but others will focus on the period since 1979. You might like to consider avoiding duplication by using these - eventually they will be 1979-2005 (poss 2006).

Trends of indices in extremes will likely be similar, but with +/- signs on maps. Nothing has been decided yet, though, and I expect a significant part of our time at LA2 will be taken up

by discussing/improving diagrams in our ZOD.

You can help us by sending comments to WG1 on the relevant parts - which are likely to be almost all.

Cheers

Phil

Cheers

Phil

At 16:47 07/12/2004, David Karoly wrote:

Hi,

As you may be aware, I am an LA for chapter 1 "Assessment of observed changes and responses in natural and managed systems" in the AR4 WGII and I have been identified as one of the points-of-contact for interactions between WGI and WGII. The chapter in which I am involved will depend heavily on inputs from a number of chapters in the WGI report. Hence, I contacting the CLAs of the relevant chapters, including chapters 2, 3, 4, 5, 6, 7, and 9, by email to discuss ways to ensure effective communication between our chapters and to avoid undue overlap between respective chapters in WGI and our chapter in WGII.

Your chapter on "Observations: Surface and atmospheric climate change" is a key chapter in WGI and it is important that what we say in our chapter in WGII follows from and agrees with your chapter. I would be very happy to discuss ways to ensure effective communication between our two chapters.

Specific aspects from your chapter of relevance to our chapter include observed changes in regional temperature and precipitation, both means and extremes. We plan to use a figure in our chapter showing a global map of observed temperature trends over the last 30 years (?) overlaid with locations of significant observed changes in natural and managed systems. We want to make sure that this is based on the same dataset(s) that you will be using to show the observed temperature trends.

In practice, almost everything in your chapter will be relevant to our chapter. I would be grateful if you could send me a copy of your ZOD after it is completed, so that I can make sure that our chapter is consistent with yours. I am happy to send you a copy of our ZOD, if you would like to read it.

I will not be coming to the WGI LA meetings until LA3, when I will be involved as a review editor. It will be important that we have already established effective communication before then.

I look forward to working with you over the next two years to ensure that the IPCC AR4 is the best possible assessment.

Best wishes, David

Colleagues,

No doubt some of you share our frustration with the current state of media reporting on the climate change issue. Far too often we see agenda-driven "commentary" on the Internet and in the opinion columns of newspapers crowding out careful analysis. Many of us work hard on educating the public and journalists through lectures, interviews and letters to the editor, but this is often a thankless task.

In order to be a little bit more pro-active, a group of us (see below) have recently got together to build a new 'climate blog' website: RealClimate.org which will be launched over the next few days at:

<http://www.realclimate.org>

The idea is that we working climate scientists should have a place where we can mount a rapid response to supposedly 'bombshell' papers that are doing the rounds and give more context to climate related stories or events.

Some examples that we have already posted relate to combatting dis-information regarding certain proxy reconstructions and supposed 'refutations' of the science used in Arctic Climate Impact Assessment. We have also posted more educational pieces relating to the

interpretation of the ice core GHG records or the reason why the stratosphere is cooling. We are keeping the content strictly scientific, though at an accessible level.

The blog format allows us to update postings frequently and clearly as new studies come along as well as maintaining a library of useful information (tutorials, FAQs, a glossary etc.) and past discussions. The site will be moderated to maintain a high signal-to-noise ratio.

We hope that you will find this a useful resource for your own outreach efforts. For those more inclined to join the fray, we extend an open invitation to participate, for instance, as an occasional guest contributor of commentaries in your specific domain, as a more regular contributor of more general pieces, or simply as a critical reader. Every time you explain a basic point of your science to a journalist covering a breaking story, think about sharing your explanation with wider community. RealClimate will hopefully make that easier. You can contact us personally or at contrib@realclimate.org for more information.

This is a strictly volunteer/spare time/personal capacity project and obviously nothing we say there reflects any kind of 'official' position. We welcome any comments, criticisms or suggestions you may have, even if it is just to tell us to stop wasting our time! (hopefully not though).

Thanks,

Gavin Schmidt

To: Kevin Trenberth <trenbert@cgd.ucar.edu>
Subject: Some weekend thoughts
Date: Mon Dec 13 09:29:24 2004

Kevin,

Read everything over the weekend, and here are a few comments. Glad I did this yesterday, as not thinking too well at the moment as daughter-in-law in labour for the last 4 hours. No news yet - just waiting !

Haven't made any alterations yet. Here are my thoughts.

3.1 I'll make a few cosmetic changes - mainly to refer to the Appendices a couple of times re significance.

Box 3.3 Reads better, will replace with this one when merge is done.

3.4 3.4.1.5 needs some work. Doesn't seem to read or flow that well.

3.4.2.1 Maybe need to expand on homogeneity tests.

3.4.2.2 4th para seems a little at odds with previous one?

3.4.2.3, 3.4.2.4 OK

3.4.3 Clouds. Needs some more work to develop a clearer message. You're aware of this.

3.4.4 Radiation. Similar comments to the cloud section. I have some specific notes for both. Despite this, probably OK for the ZOD. Maybe all we need to do is to highlight this to the reviewers.

3.5 Section seems overlong. I know you've reduced it a lot ! Contains a number of sentences where English could be improved.

3.5.1. OK

3.5.2 Significance levels for Fig 3.5.1 need some discussion. We'll need to work some on this Figure.

3.5.3 and 3.5.4 OK for the ZOD with a few better sentences.

3.5.5 and 3.5.6 Both sections seem overlong. Again know you've reduced this a lot, but if we need reductions here is a good place.

3.5.7 OK

Box 3.5 OK

3.6 Generally good.

3.6.1 OK

3.6.2 Probably remove the impact para - leave for the moment, though.

3.6.3 OK

3.6.4 I can improve this a little. It isn't all Scandinavian glaciers that are advancing, just those in SW Norway. Those in the north of Sweden are retreating.

3.6.5 OK

3.6.6/ 3.6.7 Basically OK. May need more re ACW and SAM link if we can say

anything.

3.7 This is probably too long, so would be another area for some reduction.

Agree on your suggestions for deletions as repetitive.

3.7.1.1-3.7.1.3 OK though all a little long.

3.7.1.4 This is the one where there is some repetition. Not much on monsoon.

A lot here is already in 3.8 on extremes and the Dai et al (2004) paper is now referred to in 3.3, here and in 3.8. Suggest it should just be in 3.3 and again in 3.9 (it isn't there yet).

Your figures seem in better shape than those in my section. We will likely need to work on the one Dennis is doing. Will need some colour. You're aware of which need more work from your comments. We can leave these in for reviewer and LA thoughts.

Dave has sent me a first go at the figures. Made loads of suggestions. Dave was aware colour choices poor and will be doing more on them today.

Is Chris Landsea the only person you've removed from the CA list so far? It seems so.

I should have time tomorrow onwards to do merging and send out the 3 files to all our LAs. Are you happy with me merging in your refs list? I'll keep the discard ones at end in a separate list. Still hopeful of doing all this by close of play here on Thursday. All day in London on Friday and CRU party today week from 11am onwards. Going for Dec 16 means I will only be able to get some of the Figures in 3.2 and 3.3 properly into the text.

Will send Dave's next Figure versions if they are much better. No point with current one.

Still no news !

Cheers

Phil

Phil

Attached are the three sections. Please use these for any suggested edits. Of the text, 3.7 is loosest and needs careful comparison with 3.3 to check for inconsistencies. There is model stuff in there that is not quite right or incomplete: I removed some. There is redundant ENSO-related stuff. A lot of the monsoon variability is linked to ENSO and we could say that succinctly but it would decimate what the CAs and Panmao have done. I think we will need to do this in Beijing, but I left it for now. Note the refs has a list of discards at the end.

Suggest we keep this, perhaps in a different file, and if stuff gets deleted with references, then the refs get moved there.

Some of the figures are not quite in order in 3.6 and there is the extra figure that

Date: Mon, 13 Dec 2004 11:47:16 -0500

Hi Keith,

Thanks again for your phone call, and the (informal) opportunity to help out where I can. I'm perfectly happy in that role (as an informal contributor and a formal reviewer, for example), if you and Peck, for example, are both comfortable with that.

First, "RealClimate" should be helpful. It deals w/ the skeptic claims, etc. but using the legitimate

peer-reviewed research as a basis for the discussion.

The "hockey stick" overview should be helpful:

[1]<http://www.realclimate.org/index.php?p=7>

as well as itemized responses to the various contrarian propaganda/myths:

[2]<http://www.realclimate.org/index.php?p=11>

and the specific discrediting of the claims of McIntyre and McKittrick, based both on our response to their rejected Nature comment:

[3]<http://www.realclimate.org/index.php?p=8>

and the discussion of the analysis in the Rutherford et al (2004) paper in press in Journal of Climate, that independently discredits them:

[4]<http://www.realclimate.org/index.php?p=10>

In the following emails, I'll attach some other materials (submitted papers) that deal w/ the McIntyre and McKittrick matter, and the von Storch matter,

Please let me know if there is anything we discussed that I forget to provide you. Will also draft an email to the small group (you, me, Scott, Caspar, Gene) about the prospective additional RegEM/Mann et al method model analyses,

cheers,

Mike

Date: Mon, 13 Dec 2004 11:53:16 -0500

Keith,

Attached is the Stendel et al paper (submitted to "Climate Dynamics" last month) and a corrected version of their Figure 3 (using the correct Mann and Jones NH series).

The importance of this paper is that they use the same model as von Storch (higher resolution in fact), and get a temperature history that looks much like the reconstructions/other models. Also, they appear to get the negative NAO pattern in the Maunder Minimum, which von Storch et al do not...

Again, this should be referenceable in the zero order draft, but would be good to contact Martin Stendel first about this...

Cc: k.briffa@uea.ac.uk, peltier@atmosp.physics.utoronto.ca, Eystein Jansen <eystein.jansen@geo.uib.no>

Hi Ricardo - good to hear from you. Thanks too for the interesting figure. I have some comments on this section (6.5.4) and also for the others' you're helping to lead.

Regarding 6.5.4 - I hope Dick and Keith will have jump in to help you lead, and I can too. I think the hardest, yet most important part, is to boil the section down to 0.5 pages. In looking over your good outline, sent back on Oct. 17 (my delay is due to fatherdom just after this time), you cover ALOT. The trick may be to decide on the main message and use that to guide what's included and what is left out. For the IPCC, we need to know what is relevant and useful for assessing recent and future climate change. Moreover, we have to have solid data - not inconclusive information. My take:

ENSO - coral records sensitive to ENSO (e.g., Urban et al. and Cobb et al - attached) suggest ENSO has changed in response to past forcing change (Cobb et al - updated interp by Mann et al - see recent email attachment) and recent climate change (Urban et al). Ditto for Indian Ocean - not sure if can connect to dipole - I could ask Julie Cole? NAO - lots of papers and what's the consensus? I'm not sure, but I think it is that we can't say for sure what has happened to the NAO - or AO for sure (Keith might no more - recent Ed Cook paper might be the key? - I'm not an expert here). Same thing for PDO (not an expert, but aren't their reconstructions that don't agree - see Cole et al for one - attached). In both these cases, the reconstructions don't always agree. Or do they say the NAO variability has stayed pretty constant?

Tropical Atlantic - Black et al 1999 (attached to prev email) also says 12 year mode (no consensus if dipole is the correct name for what Chang first described - see ref in Black attached) has been constant for 800 years.

Annual modes - does paleo have anything definitive to say yet? I'm a coauthor on a soon to be submitted AO reconstruction paper, but I'm not sure reviewers will go for it - nor does it match D'Arrigo's recent AO reconstruction paper (can't find).

So, the trick is for you to lead us (Dick, Keith, me - maybe Julie - ENSO expert) to produce 0.5 pages of HIGHLY focused and relevant stuff. Can you take another crack at your outline and then tell us what you need? Thanks!

Regarding 6.5.9 - can you help Dan, Ramesh and others to make quick headway on this one - it's totally missing. Thanks!

Regarding 6.3.2.1 - Keith will need help, no doubt - particularly with a good S. Hemisphere perspective (he can override me on this, but since I'm contacting you...) thanks! What do we have for the southern hem? Southern S. America, New Zealand, Tasmania, ice core?

Regarding 6.3.2.2 - what's your opinion of where this section stands?

Thanks - hope you are enjoying summer - although Tucson never gets that cold!

Best, Peck

Subject: Fw: Section on Modes of Variability

Dear IPCC colleagues

Please, find attached a preliminary draft of the proposed figure for the section: Modes of variability. The caption follows. Best regards,

Modes of variability

Figure caption. Coherent modes of climate variability across the Pacific Ocean during the past four centuries. The upper part of this figure compare temperature-sensitive tree-ring records (red triangles) from high-latitude, Western North and South America with a geochemical coral record (yellow triangle) from Raratonga, tropical South Pacific. The series shown from top to bottom are: Spring/Summer Gulf of Alaska temperature reconstruction (1600-1994; Wiles et al., 1998), Sr/Ca coral record from Rarotonga (1726-1996; Linsley et al. 2004) and annual Northern Patagonia temperature reconstruction (1641-1989; Villalba et al., 2003). Correlation coefficients between records are indicated. To facilitate the comparison, the Sr/Ca coral record is shown reversed.

Interdecadal to centennial variability in each time series was isolated by using singular spectrum analysis (SSA; lower part of the figure). For each record, all SSA reconstructed components with mean frequencies longer than 20 years were summed. Correlation coefficients between these long-term modes of variability are also shown.

Thin and thick arrows indicate coincidences in oscillations between the Raratonga and one or two high-latitude records, respectively.

Linsley, B., G. Wellington, D. Schrag, L. Ren, M. Salinger and A. Tudhope, 2004: Geochemical evidence from corals for changes in the amplitude and spatial pattern of South Pacific interdecadal climate variability over the last 300 years. *Climate Dynamics*, 22, 1-11.

Villalba, R., Lara, A., Boninsegna, J.A., Masiokas, M., Delgado, S., Aravena, J.C., Roig, F.A., Schmelter, A., Wolodarsky, A., Ripalta, A. 2003. Large-scale temperature changes across the southern Andes: 20th-century variations in the context of the past 400 years. *Climatic Change*, 59: 177-232.

Wiles, G. C., D'Arrigo, R.D. and Jacoby, G.C., 1998. Gulf of Alaska atmosphere-ocean variability over recent centuries inferred from coastal tree-ring records. *Climatic Change*, 38, 289-306.

Kevin,

I will be around tomorrow (so Dec 21) until Dec 23 inclusive. Then
again from Jan 3.

I will be checking email during the break from Dec 28 onwards.

Are you in control of the glossary additions and modifications?

As to change of base period - this seems like a decision for the
whole of WGI. To redo

the global temperature average, I can just move the series up/down,
but this isn't

the correct way to do it. I should talk out a new base period from
all the individual

stations and recalculate anomalies for the oceans. For the oceans
this isn't a

problem, but the land it is a serious problem. Many stations have
good (i.e. near

complete base periods for 1961-90) but I'll lose hundreds, maybe over
a thousand,

stations if I went to 1981-2000.

For both surface temperature and precipitation we don't have
spatially complete datasets

(like models) so it will be quite difficult.

For the circulation indices (like SOI and NAO) based on station
pairs there is a

variance term (SD). Some of the character of the series will change.
We could

easily adjust all these series by simple offsetting but it isn't
doing it properly.

I'm in the throws of a project with the HC checking all the 61-90
normals we have

for series that are incomplete, to ensure we don't have any biases.
This has taken

quite a time and I don't want to waste the effort.

The arguments of Albert and Dave make a lot of sense - continuity
with the TAR etc.

These sort of things can be explained, but then the FOD will not be
compatible with

all the papers we are referring to. This will lead to lots of
confusion. I would like to

stick with 1961-90. I don't want to change this until 1981-2010 is
complete, for 3

reasons : 1) We need 30 years and 81-10 will get all the MSU in nicely, and 2)

I will be near retirement !! 3) is one of perception. As climatologists we are often changing base periods and have done for years. I remember getting a number

of comments when I changed from 1951-80 to 1961-90. If we go to a more recent one

the anomalies will seem less warm - I know this makes no sense scientifically, but

it gives the skeptics something to go on about ! If we do the simple way, they will say

we aren't doing it properly.

Best idea might be to show some maps of 1981-2000 minus 1961-90 to show spatially

where it makes a difference for temp and precip. Showing it is quite small and likely

within the intermodel differences for years which are only nominally 1981-2000. This

might

keep both sides happy.

We also probably need to consider WGII. Also the paleo chapter will find 1981-2000

impossible. 1961-90 is difficult for them but not insurmountable.

Cheers

Phil

PS Fatima has received all the emails - her email only came to me. Not heard from

some of our LAs.

At 15:44 20/12/2004, Kevin Trenberth wrote:

Hi all

I have received comments on this from Albert, David, Dave, and Jim. Some below.

As I commented to Jim, the choice of a base period affects the zero line. In some of

our plots, namely the ones that have series of bars from the zero line to the anomaly

value, thereby infilling between the anomaly and the zero, the zero base value is

greatly emphasized. This is in contrast to a simple time series with points joined,

especially if the zero line is not also drawn. In the latter case, it is simple to move

the axis up or down to fit with the new base period. But it makes a bigger difference

to the bar plots. Now maybe that is a comment on the use and utility of bar plots,

because the relative values do not change.

The choice also affects any anomaly plots for any subperiod. But this is where the

comparison with models is most likely to occur. In this case there is a spatial pattern

to the offset, namely the difference between means for 1961-90 and 1981-2000. We could also derive that difference for certain fields and provide it to modelers to enable comparisons with our plots. For trends over certain subperiod, this makes no difference.

It seems that whatever we do, we will need an extra appendix explaining some of this and perhaps even giving plots of these differences.

In the meantime, let me suggest to those of you making computations, that you consider doing it both ways, rather than having to go back and do it over later.

Regards

Kevin

I agree with Albert, this would make comparisons with the TAR figures difficult.

Dave

Klein Tank, Albert wrote:

Hi Kevin,

My immediate response is that the choice for another base period will probably not

affect our assessment of results, but it will change all figures w.r.t the TAR. This

will be difficult to communicate and will take much more space to explain.

Albert.

Kevin

It is obviously possible to use 1980-2000 though it would require some data-processing work. The main objection is that anomalies (of temperature) would appear to be reduced relative to previous publications and readers/policymakers could become confused. A minor objection is that 1980-2000 is a bit short. Satellite data are of course in its favour. In due course, 1981-2010 will be ideal!

Clearly we hope there will be a number of diagnostic projects looking at the models over the next few months, and the more uniformly that analysis can be done the better.

> >

> > To cut a long story short, we felt that given the choice it would be most appropriate to define models' 'mean climate' by looking at the 1981-2000 mean from the all forcings 20th Century runs (or the ensemble mean if there is an ensemble). That would be consistent with the base period Chapter 10 is using for the projections. We recognise that there could be all sorts of reasons why that is not appropriate in particular cases, both scientific and practical (e.g. the observational dataset covers another period, or a longer time mean is needed because of particular modes of variability, or there is a problem with model drift or trends). So we wouldn't want to be prescriptive, but all other things being equal we would suggest that as the analysis period. If there are no show-stoppers for this, we were thinking it would be good to send out a brief email to the PIs of the diagnostic projects to request that they bear this in mind in their analysis. Jerry, there were a few other topics that might be raised in such an email and Karl Taylor will be contacting you about those.

Subject: A quick question
Date: Tue Dec 21 11:39:09 2004

Kevin,

No idea how Chris Folland got this. Presumably David Parker forwarded it !

Anyway, it doesn't matter. The questions are:

When will you be sending me your signed-off draft?

Will this be the complete doc file of text?

Will you be modifying any of the figures?

On the latter just want to know if I'm keeping track of figs as well as Refs. I've got the two you sent last night.

I'll be off from 5pm on Dec 23. I'll begin reading the draft from Dec 29. Will likely be in at least once on Dec 29-31, but will be checking email from Dec 29.

Cheers

Phil

All

As someone who dealt with these matters in the past, a decision about the climate normals period was regarded as so important that all of WG1 debated it and agreed the outcome. So that should be the route again, I believe, if a change is wanted. From a personal perspective, I tend to agree with Phil that this time we should stick (in general) to 1961-90 normals, and that IPCC 2013 should perhaps change to 1981-2010.

Having said that, we may produce 1981-2000 normals in the next year for SST if we can solve adequately remaining problems (for climate change monitoring) with satellite SSTs. A key goal is monitoring changes in the Southern Ocean. Solutions are likely to include use of some corrected (to bulk SST data) ATSR data. This depends on work elsewhere in the Met Office. However, some less well corrected AVHRR data is needed as well to extend normals adequately back to 1981 in much of the Southern Ocean. This may give a new perspectives on the southern ocean SST changes; are likely to be significantly different in the southern half of the southern ocean from the global average. This is suggested by the lack of reduction of Antarctic sea ice, in contrast to the Arctic, which still persists. Such work may or may not get into IPCC FAR but if it did, it could be a special case. But it would need careful handling for conversion to advice to policy makers.

Chris

Hey Keith,

I hope your visit w/ your family went well...

I went ahead and tried to make some constructive comments on what you sent (figured it would be nice to get this out of the way before the holidays come round)..

Let me say I think it's shaping up very nicely--looks like it should be a significant improvement on the '01 report. You've handled the various controversies and points of dispute delicately and adeptly, while still driving home in the end the key point (that the evidence appears to point to anomalous late 20th century behavior).

I made a dozen or so minor comments--please make use of them as you see fit.

Lets reconvene on this after the holidays. Thanks again for including me in and giving me an opportunity to comment.

I hope the rest of your holidays go well,

mike

Peck and Eystein

I have to break off now for the christmas period

This is unavoidable. I am sending what I have now

even though I am not at all happy with it.

It is obviously only part way there. Getting the data to produce Figures and work out how to design them is going to be time very consuming and I will rely entirely on Tim here to do them

- and the regional input

stuff if wanted will need input from a number of people that I have not been able to contact (see later)

The borehole discussion (contributed to by Henry Pollack) will need batting around and Henry (and Mike , who contributed a section on regional forced changes) will need to be kept on board. There will be loads to say on the simulated temperature histories and Tim will help here also

- but much is unpublished or

even unanalysed (hence Simon and Eduardo will need to contribute eventually). The glacier bit at the end is what Olga sent and I have not had time to work through it.

You two need to give some direction as to how

much you wish to have explicitly looking at the mass of NAO?AO reconstructions , ditto ENSO or PDO and all the

simulations of these - but at this stage not sure where in overall plan all this going. Do we really want a discussion on MWP

and LIA per se ? The regional descriptions , including Southern Hemisphere could be infinite length and I suppose we should only discuss longest or pre assimilated information - but will need specific input here from colleagues if we are to do these regional (including precipitation) sections .

I know Julie and Ed , and presumably Eystein , will be the best people to ask.

I am attaching the current text and placeholder ideas for Figures .

Not feasible to work more on these until know wider priorities re space.

Have had bad experience with ENDNOTE - and Tom Melvin here will forward the biblio file later.

I wanted to do more , but that is all I can manage til after Xmas

Here is wishing you (and your loved ones) all the best

Keith

Phil,
I would immediately delete anything you receive from this fraud.
You've probably seen now the paper by Wahl and Ammann which independently exposes McIntyre and McKittrick for what it is--pure crap. Of course, we've already done this on "RealClimate", but Wahl and Ammann is peer-reviewed and independent of us. I've attached it in case you haven't seen (please don't pass it along to others yet). It should be in press shortly. Meanwhile, I would NOT RESPOND to this guy. As you know, only bad things can come of that. The last thing this guy cares about is honest debate--he is funded by the same people as Singer, Michaels, etc...
Other than this distraction, I hope you're enjoying the holidays too...
talk to you soon,
mike

Dear Phil,

I have noticed the following statements in Rutherford et al [2004], in which you are a co-author. As compared with some of your co-authors, I get the impression that, while you feel very strongly about your views, you are also concerned with getting to the bottom of matters and are less concerned with scoring meaningless debating points. In this spirit, I draw your attention to some incorrect statements in Rutherford et al. [2004] concerning our material. There is really a quite serious problem with the PC methods in MBH98 and the comments made in Rutherford et al [2004] are really quite misleading. For the reasons set out below, I request that these comments be removed from the manuscript.

Regards, Steve McIntyre

Sent: Tuesday, December 28, 2004 1:48 PM
Subject: Rutherford et al. [2004]
Dear Dr. Randall,

Recently, at the website [7]www.realclimate.org, Michael Mann publicized a submission by Rutherford et al. to Journal of Climate, entitled Proxy-based Northern Hemisphere Surface Temperature Reconstructions: Sensitivity to Method, Predictor Network, Target Season, and Target Domain. This paper contains some untrue statements and mischaracterizations regarding criticisms we (McIntyre and McKitrick) made of Mann et al. (1998) [MBH98] in a 2003 paper and subsequent exchanges under the auspices of Nature. We are writing to request that these untrue statements be removed from the paper before any further processing of the document by Journal of Climate takes place.

First, Rutherford et al. states that McIntyre and McKitrick [2003] used an incorrect version of the Mann et al. (1998) proxy indicator dataset. The history of this matter is

summarized below (all relevant emails and other documentation are available at [8]<http://www.climate2003.com/file.issues.htm> .

In April 2003, we requested from Mann the FTP location of the dataset used in MBH98. Mann advised me that he was unable to recall the location of this dataset and referred the request to Rutherford. Rutherford eventually directed us to a file (pcproxy.txt) located at a URL at Manns FTP site. In using this data file, we noticed numerous problems with it, not least with the principal component series. We sought specific confirmation from Mann that this dataset was the one used in MBH98; Mann said that he was too busy to respond to this or any other inquiry. Because of the many problems in this data set, we undertook a complete new re-collation of the data, using the list of data sources in the SI to MBH98 and using original archived versions wherever possible. After publication of McIntyre and McKittrick [2003], Mann said that dataset at his FTP site to which we had been referred was an incorrect version of the data and that this version had been prepared especially for me; through a blog, he provided a new URL which he now claimed to contain the correct data set. The file creation date of the incorrect version was in 2002, long prior to my first request for data, clearly disproving his assertion that it was prepared in response to my request. Mann and/or Rutherford then deleted this incorrect version with its date evidence from his FTP site.

It is false and misleading for Rutherford et al. to now allege that we used the wrong dataset. We used the dataset they directed us to at their FTP site. More importantly, for our analysis, to avoid the problems with the principal component series, we re-collated the tree ring data identified in MBH98 from ITRDB archives, calculated fresh principal component series; in addition, we re-collated other proxy data from archived versions wherever possible. Thus, our own calculations were not affected by the errors in the supplied file as we did NOT use the incorrect version in our calculations. To suggest otherwise, as is done in Rutherford et al [2004], is highly misleading. To date, no source code or other evidence has been provided to fully demonstrate that the incorrect version (now deleted) did not infect some of Manns and Rutherfords other work. In this respect, we note that the now deleted file pcproxy.txt occurs in a legend in a graphic at Rutherfords website, indicating possible use elsewhere by Rutherford of the incorrect version.

Accordingly, we request that the above claim be removed from the manuscript.

Secondly, Rutherford et al. [2004] argues that the difference between MBH98 results and MM03 results occurs because of our misunderstanding of a stepwise procedure in MBH98 for the calculation of principal component series for tree ring networks. Again, this claim is misleading on its face. While our 2003 paper did not implement the (then undisclosed) stepwise procedure, as soon as this matter was raised in subsequent correspondence in November 2003, we implemented it and we continued to observe the discrepancies in principal component series and final results. The current manuscript ignores a refereed

exchange at Nature in which we specifically clarified (in response to a reviewers question) that we had obtained such results while using the exact stepwise procedure described in MBH98. Mann is aware of this refereed exchange.

The reason for the difference between our results and MBH98 results is primarily due to the fact that the tree ring principal component series in MBH98 cannot be replicated using a conventional principal components method. The MBH98 principal component series can only be replicated by standardizing on a short segment a procedure nowhere mentioned in MBH98 and only recently acknowledged in the SI to the Corrigendum of Mann et al. [Nature 2004] in response to our concerns on the subject expressed to Nature. In effect, MBH98 did not use a conventional centered PC calculation, but used an uncentered PC calculation on de-centered data. The impact of this method is the subject of ongoing controversy, which is well-known to the authors, but the existence of the method in MBH98 is no longer in doubt. In discussions of PC calculations in 2004 exchanged with the authors through Nature, we implemented the stepwise procedures of MBH98 referred to in the present manuscript and demonstrated that important differences remain even with stepwise procedures, as long as the uncentered and decentered methods of MBH98 are used. The differences in PC series resulting from using centered and uncentered series has been fully agreed to by all parties in the Nature exchange, although the parties continue to disagree on the ultimate effect on final NH temperature calculations. Accordingly, the discussion in Rutherford et al. [2004] is very incomplete and misleading in this respect. While we recognize that Mann et al. have argued that they can salvage MBH98-type results using alternative methodologies (e.g. increasing the number of PC series used in the 1400-1450 period), these salvage efforts are themselves a matter of controversy and do not validate the claims being put forward in the Rutherford et al. paper.

Accordingly we ask that this claim also be deleted from the manuscript.

Regards,
Stephen McIntyre and Ross McKittrick

Hi Keith - Happy new year. Hopefully, you had a good holiday. I've had a chance to read your section and hopefully you've had a chance to read what I sent just before the holidays. The purpose of this email is to help get a focus on the finish line (just a few days away) and to get a dialog going that will hopefully help you finish section 6.3.2.1. If you'd like to talk on the phone, just let me know.

Please see my email from right before xmas holidays for original comments. Plus, here are the new ones from both me and David Rind:

0) as leader of this KEY section, we need you to take the lead integrating everything you think should be integrated, editing and boiling it down to just ca 4 pages of final text (e.g., 8 pages of typed text plus figs). This means cutting some material (e.g., forcings and simulations) and perhaps moving glacier record (MUCH boiled down) to a box. See below.

00) note that we can also perhaps move some of the details to the appendix (although we won't write this until after the current ZOD crunch, save an outline of what you might want in there).

1) I like your figure ideas, with the comments:

1a) I don't think you need figure 1d - the SH recons are sketchy since not much data, and it might be better to just discuss in a sentence or three. Any space saved is good too. Not sure about your proposed 1e - have to see it, I guess.

1b) Figure 2 looks interesting. I'm trying to get the latest Arctic recon from Konrad Hughen - it is quite robust and a significant multi-proxy update. Should be published in time, though not sure thing since he's still hot on including his (our) AO recon which is more sketchy

1c) I think we can save space and improve organization if we DO NOT include Fig 3. However, this is open for debate - see David's comments below.

2) I agree with David's comments in general - so see them below. The prickly issue is where to put the forcings and simulated changes. I am close to having the prose from the radiation chapter, including the latest Lean and Co's view on solar - this will make many of the existing simulations involving inferred past solar forcing suspect (I will send in a day or so I hope). This means that we might be best saving space and downplaying this work some. I'm not sure, but wanted to debate it with you. Also, Chap 9 will have simulations in spades, so we can save space by letting them do it. Also, as David points out, we can focus on it elsewhere in our chapter more concisely - leaving you to focus on the VERY important obs record of temp and other changes. Can you tell, I'm still not 100% sure? I'll send another email to you and others about this in a bit.

3) Your section is too long and needs to be condensed. Thus, you need to think through what's most important and what's less so. For example, we need to figure out how to condense the glacier record of change. David thinks it should be a separate section that cuts across time scales (i.e., Holocene and last 2000 years). Perhaps we should try to make it into a box - 3 to 5 short paragraphs and a figure or two. Either way we have to really wack it. What do you think - you and I should be on the same page with Eystein before discussing w/ Olga perhaps. Or you can discuss with her - you're the lead on this section.

4) you're doing an impressive job! Lots to keep track of.

Next, here is what David has offered. Take it all with a grain of salt, but I have read it and he has many good points. On the structural or any other points, I'm happy to discuss on the phone, or you can just debate with him and me on email.

***** From David Rind 1/4/05 *****

6.3 Understanding Past Climate System Change (forcing and response)

6.3.1 Introduction (0.5 pages)

6.3.2 The Current Interglacial

6.3.2.1 Last 2000 years (4 pages)

Figure 1 should be of the last 2000 years, with appropriate caveats, not just since 1860 (which will undoubtedly be in other chapters).

pp. 8-18: The biggest problem with what appears here is in the handling of the greater variability found in some reconstructions, and the whole discussion of the 'hockey stick'. The tone is defensive, and worse, it both minimizes and avoids the problems. We should clearly say (e.g., page 12 middle paragraph) that there are substantial uncertainties that remain concerning the degree of variability - warming prior to 12K BP, and cooling during the LIA, due primarily to the use of paleo-indicators of uncertain applicability, and the lack of global (especially tropical) data. Attempting to avoid such statements will just cause more problems.

In addition, some of the comments are probably wrong - the warm-season bias (p.12) should if anything produce less variability, since warm seasons (at least in GCMs) feature smaller climate changes than cold seasons. The discussion of uncertainties in tree ring reconstructions should be direct, not referred to other references - it's important for this document. How the long-term growth is factored in/out should be mentioned as a prime problem. The lack of tropical data - a few corals prior to 1700 - has got to be discussed. The primary criticism of McIntyre and McKittrick, which has gotten a lot of play on the Internet, is that Mann et al. transformed each tree ring prior to calculating PCs by subtracting the 1902-1980 mean, rather than using the length of the full time series (e.g., 1400-1980), as is generally done. M&M claim that when they used that procedure with a red noise spectrum, it always resulted in a 'hockey stick'. Is this true? If so, it constitutes a devastating criticism of the approach; if not, it should be refuted. While IPCC cannot be expected to respond to every criticism a priori, this one has gotten such publicity it would be foolhardy to avoid it.

In addition, there are other valid criticisms to the PC approach. Assuming that the PC structure stays the same was acknowledged in the Mann et al paper as somewhat risky, given

the possibility of altered climate forcing (e.g., solar). Attempting to reconstruct tropical temperatures using high latitude PCs assumes that the PCs are influenced only by global scale processes. In a paper we now have in review in JGR, and in other papers already published, it is shown that high latitude climate changes can directly affect the local expression of the modes of variability (NAO in particular). So attempting to fill in data at other locations from PCs that could have local influences may not work well; at the least, it has large uncertainties associated with it.

The section from p.18-20 - simulations of temperature change over the last millennium , including regional expressions - should not be in this section. It is covered in the modeling section (several different times), and will undoubtedly be in other chapters as well. And the first paragraph on p. 19 is not right - only by using different forcings have models been able to get similar responses (which does not constitute good agreement). The discussion in the first paragraph of p. 20 is not right - the dynamic response is almost entirely in winter, which would not have affected the 'warm season bias' paleoreconstructions used to prove it. It also conflicts with ocean data (Gerard Bond, personal communication). Anyway, it's part of the section that should be dropped.

pp. 20-28: The glacial variations should be summarized in a coherent global picture. Variations as a function of time should be noted - not just lumped together between 1400 and 1850 - for example, it should be noted where glaciers advanced during the 17th century and retreated during the 19th century, for that is important in understanding possible causes for the Little Ice Age (as well as the validity of the 'hockey stick'). The discussion on the bottom of p.25-27 as to the causes of the variations is inappropriate and should be dropped - note if solar forcing is suspect, every paragraph that relates observed changes to solar forcing will be equally suspect (e.g., see also p. 44, first paragraph).

Bottom of p. 27: Greene et al. (GRL, 26, 1909-1912, 1999) did an analysis of 52 glaciated areas from 30-60N and found that the highest correlation between their ELA variations in the last 40 years was with summer season freezing height and winter season precip. The warm season freezing height was by far more important. Therefore, the relationship of glacier variations to NAO changes (which are important only in winter), as discussed in this paragraph, while perhaps valid for a period of time in southern Norway, is not generally applicable.

p. 34-36 on forcings: note that this is redundant to what is discussed in several later sections (e.g., 6.5.2); and other chapters), and that is true of forcing in general for the whole of section 6.2. I would strongly suggest dropping forcing from section 6.3.2.1, at least, and perhaps giving it its own number, or referring to othersubsections for it. It has a different flavor from the responses, and the section is already very big. Forcing does need to be discussed in the paleoclimate chapter, for reasons of climate sensitivity and explaining observations, but that is what Chapter 6.5 is about.

(In summary - 6.3.2.1 already is taking on one controversy - paleotemperatures, which is needs to do better, It should not have to deal with the forcing problems as well, and especially not in an off-handed way.)

Specific comments: p. 36: 6 ppm corresponds to a temperature response of 0.3 to 0.6°K using the IPCC sensitivity range.

p. 36, last paragraph: one could equally well conclude that the reconstructions are showing temperature changes that are too small. This is the essence of the problem with the last 2000 years: if the reconstructions are right, either there was no solar forcing, or climate sensitivity is very low. If the real world had more variability, either there was solar forcing, or climate sensitivity is high (as is internal variability). I've tried to say this in the climate sensitivity sub-chapter.

pp. 37-41: obviously a lot of overlap, but it shouldn't be hard to combine these.

p. 39, first paragraph: but can the models fully explain what is thought to have happened? Quantification is important here, because many of the same climate/veg models are being used to assess future changes in vegetation.

p. 42 - first full paragraph: what are the implications of the methane drop without a CO2 drop?

p. 43, middle paragraph: obviously should mention solar-orbital forcing in this paragraph.

p. 44, first paragraph: again, assuming a solar forcing

p. 45, first paragraph: overlap with pp. 20-28.

Second paragraph: overlap with p.39, last full paragraph

p. 52 - repeat of p. 43.

***** END From David Rind 1/4/05 *****

Thanks! Cheers, peck

Hi Keith - great (!) to hear from you - hope you had a good holiday.
Your reward (ha) is the attached paper and comment below from Konrad.
He can supply data if needed for a synthetic figure, but we can add
this later once the Science paper he mentions (w/ us a co-authors
among millions, I assume) gets vetted more. Your call.

I'm still not convinced about the AO recon, and am worried about the
late 20th century "coolness" in the proxy recon that's not in the
instrumental, but it's a nice piece of work in any case.

Now, for all the issues you raise on other stuff in your email, I'll
address to you and that crowd.

thanks, Peck

Hi Keith and Co - I think David likes a good debates, so the main thing is to consider his comments and respond appropriately. Although the first priority has to be on the ZOD text and display items, maybe you can go back over his comments AFTER the looming deadline and further discuss things with David and others. For now, just work away.

The biggest issue is how to handle forcing and simulations - i.e., where to put different pieces in the chapter. Eystein and I will help the team work through this. More soon, but for now just proceed as you have been proceeding. There is real merit to the concept that your section is about how climate varied over the last 2ka, and what caused these variations. The flip side is that we need to get a clear vision of how this differs from what goes into the other sections. Eystein and I will work more on this asap.

Your plan re: glaciers is good. That's a tough one, but it has to be boiled WAY down. Moreover, my gut is to focus on the extent to which these complicated natural archives (e.g., complicated by ppt change) support or do not support the other proxy evidence/conclusions. This is why I was thinking we might think about a box, and to include the Lonnie perspective in it - e.g., glaciers are now melting everywhere (almost - we know why they are not in those places) in a manner unprecedented in the last xxxx years. Make sense? See what Olga says, and if needbe, I can help focus that stuff more.

Thanks! Peck

Neil,

Just to reiterate David's points, I'm hoping that IPCC will stick with 1961-90.

The issue of confusing users/media with new anomalies from a different base period is the key one in my mind. Arguments about the 1990s being better observed than the 1960s don't hold too much water with me.

There is some discussion of going to 1981-2000 to help the modelling chapters. If we do this it will be a bit of a bodge as it will be hard to do things properly for the surface temp and precip as we'd lose loads of stations with long records that would then have incomplete normals. If we do we will likely achieve it by rezeroing series and maps in an ad hoc way.

There won't be any move by IPCC to go for 1971-2000, as it won't help with satellite series or the models. 1981-2000 helps with MSU series and the much better Reanalyses and also globally-complete SST.

20 years (1981-2000) isn't 30 years, but the rationale for 30 years isn't that compelling. The original argument was for 35 years around 1900 because Bruckner found 35 cycles in some west Russian lakes (hence periods like 1881-1915). This went to 30 as it easier to compute.

Personally I don't want to change the base period till after I retire !

Cheers

Phil

At 09:22 05/01/2005, Parker, David (Met Office) wrote:

Neil

There is a preference in the atmospheric observations chapter of IPCC AR4 to stay with the 1961-1990 normals. This is partly because a change of normals confuses users, e.g. anomalies will seem less positive than before if we change to newer normals, so the impression of global warming will be muted. Also we may wish to wait till there are 30 years of satellite data, i.e until we can compute 1981-2010 normals, which will then be globally complete for some parameters like sea surface temperature.

Regards

David

Olga
am sending this to get you in this loop re the discussion for slimming down the 2000 year section Basically , IN THIS BIT - the decision is to reduce the glacier evidence to a very much smaller piece , coached in the sense of how the glacier evidence is problematic for interpreting precise and quantitative indications of the extent of regional or Hemispheric Warmth (and even cold) - issues of translating tongue position or volume into specific temperature and precipitation forcing . Hence , I am having to remove the stuff you sent and am asking if you could consider trying to write a brief section dealing with the issues I raise ? I also attach some initial comments by David Rind (on the full first draft of the chapter sent round by Eystein) for consideration Sorry about this - but presumable (as you suggested earlier) some of this can go in the 10K bit. You can shout at me (and the others) later!
cheers
Keith

Make sense? See what Olga says, and if needbe, I can help focus that stuff more. Thanks! Peck

Hi Peck (et al)

I am considering comments (including David's) re last 2000 years - some are valid = some are not . Will try to chop out bits but we need this consensus re the forcing and responses bit - I am for keeping the forcings in as much as they relate to the specific model runs done - and results for last 1000 years as I suspect that they will not be covered in the same way elsewhere . David makes couple good points - but extent to which forcings different (or implementation) perhaps need addressing here. The basic agreement I mean is that the recent warming is generally unprecedented in these simulations. It will take time and input from the tropical ice core /coral people to do the regional stuff well . I think the glaciological stuff is a real problem - other than just showing recent glacial states (also covered elsewhere) - of course difficult to interpret any past records without modelling responses (as in borehole data), but this requires considerable space . My executive decision would be to ask Olga to try to write a couple of paragraphs on limits of interpretation for inferring precisely timed global temperature changes? What do others think? I only heaved Olga's stuff in at last moment rather than not include it - but of course it needs considerable shortening. The discussion of tree-ring stuff is problematic because it requires papers to be published eg direct criticism of Esper et al. We surely do not want to waste space HERE going into this esoteric topic? All points on seasonality , I agree with , but the explicit stuff on M+M re hockey stick - where is this? ie the bit about normalisation base affecting redness in reconstructions - sounds nonsense to me ?

I have to consider the comments in detail but am happy for hard direction re space and focus. If concensus is no forcings and model results here fine with me - Peck and Eystein to rule

Keith

Susan,

Thanks for the quick reply. Kevin might have thoughts, but I'll give it some thought over the next few months. It isn't crucial till well after our second meeting.

Kevin can relay our thoughts on references next week, and we can come up with specific suggestions here if these need to be discussed with WG2 and WG3 before all the second lead author meetings. I know we can reduce our number of references with more work, but I suspect we will be requested at the time of the FOD and SOD (and maybe the ZOD) to consider many others. A lot of NMSs, University Depts. and Research Institutes measure success as seeing their work cited by IPCC ! I reviewed KNMI this time last year and they did exactly this. This shouldn't be a measure, but we will likely be under pressure to cite many more papers for this reason.

Cheers

Phil

At 13:58 06/01/2005, Susan Solomon wrote:

Phil,

Happy new year to you too. It's good to hear that your chapter is progressing well. I'll see Kevin next week at the AMS meeting and perhaps we can discuss its high points, along with the more basic issue of references, etc.

You've raised a number of concerns that are always an issue not only for IPCC but also for other assessments and even for our own individual key papers at times. But you have made no suggestions as to how to deal with them.

Could you please let me know if you have any suggestions to put forward?

Thanks,

Susan

ricardo@lab.cricyt.edu.ar

Hi Keith,

May I have your part of the text (2ka) to have a look, please. As far as I understand we decided to have glacier fluctuations separately in a frame. In this case, shall we keep glacier variations in the Holocene or we will extract it to place in this frame? I will contact Georg Kaser (ch 04) to see what they already have to comment on glacier/climate links. They must have treated this problem already. Besides it is more natural to consider it using the instrumental data. In this case we will deal with the paleo problem only, i.e. the dating of moraines, the erased traces of old advances, the use of lacustrine deposits to reconstruct the glacier erosion (size), the reconstruction of former ELAs, the sizes of retreated glacier etc. Shall we discuss the accumulation reconstructed from the ice cores or it will be just the problem of glacier front variations?

Another possibility is to have a common frame with the ch 04: How glaciers reflect climate and what they say about the climate in the Holocene (last 2ka).

I need the answers before I begin.

Please notice the change of my e-mail address. I will check both addresses a while, but have to move to a new one olgasolomina@yandex.ru

Regards,
olga

I agree; Keith should have the room, and section 6.5.8 should be compatible - has Fortunat followed the discussion between David/Stefan. Can you guys (David, Stefan, Keith, and Fortunat) ensure this?

Thanks, Peck

Valerie,

Thanks for putting together the chapter so well. I think it is quite comprehensive now. I have made a few changes in the enclosed document and also added a comment (pops up if you mark the yellow field).

I tend to like the questions, and think it highlights the relevance elements of the chapter. The missing references I have suggested, we can take care of in the final editorial process from our side.

As for figures one figure showing the evidence for Holocene warmt and the abrupt character of the 5-4ka cooling, perhaps with a low latitude data set that shows another evolution would be good to have, as you indicate, but we cannot bombard the chapter with wiggly lines, so the most characteristic examples would be best.

If you need high lat.ocean data I can provide, or perhaps NorthGrip 0-18 is best?

Cheers,

Eystein

gif.fr>, Keith Briffa <k.briffa@uea.ac.uk>

Hi Prof. Zhang: thanks for your email and good to hear about your book. I will send the reference file to the LAs for them to incorporate as appropriate. You will also be editing the ZOD when it's complete, or of specific sections before then if you ask the appropriate leader of a section of interest (see previous listserv email with this list in case you don't remember from Italy).

Regarding 6.5.9, I will cc this to Dan and Ramesh so you can coordinate with them directly. This is the process we have adopted for all subsections so we don't waste time with the CLA's having to relay messages. Go direct...

I will also CC to Jean-Claude and Keith, so they make sure they have checked your input.

Many thanks, Peck

+@Dear Peck:
...

As regards Section 6.5.9 I shall do my utmost to help Den and Ramesh. But the assistance is to come only after I have read through their draft . Only in that way can I form an ideal "it must be relevant to policy makers" . I have been accustomed to write about scientific facts. Now I am confronted with a new problem how to serve the purpose of another style. Otherwise my suggestions would be of no use.

I had sent paragraphs to Jean-Claude for Section 6.2.2 and to Keith Briffa for section 6.3.2.1. last Nav..

With best wishes,

Eystein

in theory - it is supposed to be finished. I would just remove the two sections I suggested (or certainly move the regional simulation stuff into Ricardo's section. How does end note cope with references that are not published?

Keith

At 13:26 12/01/2005, you wrote:

Hi Keith,

I am in transit back to Bergen where there is a strong storm at present, but just a query to ask what you think a realistic time frame for your part. I will be reading through it on the way. If you have problems getting the references in, this is something we can help with, if you just write in text author name, year and paper, then we download from the ISI base and enter into End Note here, just to help you prioritising the text and figures.

Thanks for all your efforts. This is a critical part of the Chapter and the most complex and it seems to progress well, despite the strains.

Cheers,
Eystein

Basically, I need to send this to you to because there comes a point when I am just not able to read it objectively.

I would really like you both - and David and Stefan (I am ccing to them only) to look at it. Obviously it has grown too much, but the information in here is in my opinion all important.

I suggest removing the regional simulations stuff from the end (as David said earlier!) but feel this should be somewhere - also (sorry Eystein) perhaps the ocean section should go? I have dropped the proposed Figure 2 - after wasting a lot of time on it - there are too many problems with getting and understanding data - and then making any sensible conclusion on the basis of it. We really must have the two Figures left though - or some variants (these need borehole curves including and some way of indicating envelope of uncertainty around all reconstructions - perhaps as gray shading of different darkness depending on how many confidence limits overlap).

I would really appreciate a dispassionate look by all of you at the conclusions drawn after the the description of both Figures - in the light of the discussion we had about interpreting these Figures. I am really happy if you and David and Stefan (and Fortunat?) consider what is worth and not worth trying to say re the implications of these Figures, beyond the TAR. I can not tell if what I am saying is balanced (I know

Esper reconstruction is very hairy and ECHO-G run has much too great long-term variability - but no evidence PUBLISHED to support this - yet at least). Is what I say about the implications of the reconstructions banal?

I have been battling with teaching today and fucked up course scheduling by the administration that has outraged some students. Tomorrow I must take daughter back for new term in Cambridge - and now must work on proposal for Russian who leaves Thursday and needs to submit before then.

Do have a look and trim , cross reference as needed. The nightmare with these references continues also and I will have to get someone to help out here - incidentally our secretary has gone absent for a month . I will be back in hopefully by tomorrow afternoon . The conclusions (bullets?) should be very brief - but can not see them yet - suggestions welcome

I can try to do something for the methods but would rather you just told me exactly what is needed. I will then work on this Thursday and likely happy to accept what you say re this text. I know I have not contributed to the discussing on other sections - very frustrating - but must wait til after ZOD . Sorry

Keith

Hi all on the list above... Some of you have received this already
straight from David, but
some other key people have not. Eystein and I would appreciate it very
much if you would
please read/comment/and edit the attached section 6.5.8 (Sensitivity)
NO LATER THAN
THURSDAY NOON, Eastern time (6PM GMT).

Please send responses to all on the address list ABOVE, plus Peck.

Thanks, Peck

Dear Fortunat (and others),

Here is the revised section 6.5.8. I've put in most of your changes
(and also most of
those suggested by Stefan, particularly with regards to clarifying
the sign of the
radiative forcing). Most importantly, I've removed the table - I
agree it seems to imply
a solidity that is really not there. The one thing I have not done
is condense it
greatly (of course!). The real reason for going into such detail,
rather than just

saying, "well, the forcing and response are uncertain, so we can't conclude anything",
is I think it's important to show that paleoclimate scientists have gone to some effort
to try to deduce climate sensitivity from the paleorecord, the parameter that is
probably of most interest to IPCC. In that respect the details are important, as are the
magnitudes of uncertainty represented in the different studies. Obviously, at any point
in the proceedings the section can be shortened, but I thought it useful to start with
this level of quantification, and show paleoclimate has this similarity with the rest of
IPCC in addition to more qualitative concepts.

I've responded to your individual comments below.

At 6:15 PM +0100 1/11/05, joos wrote:

Dear David,
Here my comments on the updated climate sensitivity section. Please apologize if I formulate my comments straight away, but I need to leave
very soon. Many of my comments might have to do with presentation. Your main conclusions in paragraph f are fine.
My view is that it would be ideal to address the issue from a probabilistic view point. this is of course not always possible.
1) Maunder Minimum section:
Several studies using Monte Carlo approaches show that almost any climate sensitivity is possible when taking into account
uncertainties
in radiative forcing input data as well as observational records over
the 20 century as constraints. See the Paris report for more information.
The uncertainty does not only arise from indirect aerosol effect,
but
also form the whole range of forcing agents that all have an uncertainty
attached. E.g. Reto Knutti did some evaluation of his results where
he
assumed that the aerosol forcing is exactly know (No error) -> even
then
climate sensitivity remains unconstrained. Clearly, uncertainty is growing when going further back in time than the last century as
done
here. Then, the numbers provided in the table are useless, as you
now
state in the last sentence of the revised text.
2) Other sections:
I think similar concerns also hold for the other sections. For
example,

the LGM global cooling is very uncertain. I have just heard yesterday a

talk by Ralph Schneider who showed how different SST reconstructions (Alkenone, Cd/Ca, MAT, radiolare etc) disagree. global SST cooling might be anywhere between 0 and 4 K or so. Of course, CLIMAP and the recent GLAMAP update provide a reasonable estimate. However, the point is that uncertainties are huge.

The table is a very focused and stand alone thing for the reader. It gives the impression that climate sensitivity for different period can be well evaluated. However, this is not the case.

3) My conclusion:
- The table should be dropped. I have quite a strong feeling here, as it seems to me that the number in the table are very hard to defend and should not be made prominent.

The table and reference to it has been dropped.

- The whole section should be condensed considerably. Your main conclusions in paragraph f are fine.

Well, removing the table will shorten this section!

Further comments:

1) section d) 1. para: solar forcing reduction estimate range up to 0.65% for MM e.g. Reid, 97 and Bard et al.

Correction made, and reference added (and I also corrected the numbers as Stefan suggested, although the upper number is actually larger given the Reid estimate).

2) section d, last para equilibrium
The statement that transient effects are not important is very hard to defend:

2a) The warming and forcing up to today is considered. Certainly, we are now far from equilibrium (a lag of 30 years or so).

2b) the volcanic forcing is very pulse like and I do not see how the equilibrium concept holds here. It can only be evaluated in a transient way.

3c) The MM is probably not in equilibrium climate, as solar forcing has likely varied over the MM as indicated by radiocarbon, although sunspots

were not present

I've removed the word "transient" but I have justified the equilibrium aspect of the sentence with a reference (we investigated that issue by running from 1500 through the Maunder Minimum, and seeing what the prior changes in solar forcing did to the Maunder Minimum cooling - the effect, as noted in the reference, was small in our model).

3) section b) end of 1. para: How should such a 'general climate sensitivity' be defined?

For now I've simply suggested what should also be factored in; I don't know that it's our place to come up with a new definition per se, although if IPCC is interested, we could try!

4), section c) Somewhat a mix of model and observations. end of 2 para:

It is not clear which forcing was operating in these different models (at least it is not stated in the text) and hence one can not directly imply a climate sensitivity in the way done here. For this the forcing that went into the model simulations must be known.

I looked at each of the references and saw what forcing they actually used - they were all very similar except for one which used current orbital parameters (not really important). This comment is now included.

Hope this is useful and looking foreward to further debate the issue.

Thanks for the comments!

David

ps - Jonathan, the attached Endnote library includes the references we discussed yesterday, as well as all the ones relevant for this section.

<x-flowed>

Hi all: Keith and Tim asked for specific requests in terms of what you could do for section 6.2.2. I'm hoping Valerie and Fortunat have already made enough progress that they can ask, but here's my take:

1. you have lots of methodology material in your 6.3.2.1, and this is good. It would be good to refer to this from the earlier, more general 6.2.2
2. the goal of 6.2.2 is to give the reader more confidence in paleo and to get them to read on with confidence that what they read will be of use
3. I suspect that the format V and F will be working around will be one that can first highlight chronological issues (that we can date some proxies very well, and that's what we focus on in this chapter primarily). It would be good to have the usual comforting comments about tree rings and other annual proxies.
4. The, it would be good to have the basics on how proxies reflect climate, and how we know we understand the relationship. That it is useful even if the proxy is responding to things other than climate. Seasonality, etc. Include brief overview of calibration, verification. you know the drill.
5. keep it short and not too detailed. Use lots of references - including to the most recent stuff.
6. I'm sure we'll end up modifying/improving later after we figure out what to do with the appendix
7. Need to work fast, very fast, but hopefully V and F have made real progress already.

Thanks!! Peck

Keith, Tim (and friends- please read below and provide your comments THURS too) - just finished reading your draft and my primary reaction is one of great relief and admiration. You've done an excellent job. I'm sure things will look different in the end, but for the ZOD, this lays things out just fine.

That said, here are comments. More are in the attached draft w/ track changes

1. still need to see the figs - ok to state what still has to be done (as you have)
2. regarding the ocean section, I think some of it should stay in - both as a placeholder for other relevant stuff, and because it is important. See attached. It would be good if EYSTEIN would look at my comments for this section and provide the needed minor help - we need the punchline/bullet - how does the 20th century compare with the previous part of the record (you say it shows the warming, but then don't go the next step.
3. THIS IS THE ONLY COMMENT THAT WILL TAKE MORE THAN A FEW MINUTES - can we get THE word on the MWP in before hydro? Heck, I'd even support a small (smaller than the other ones) box. There is lots of debate about the MWP,. and we need to weigh in. Was it global, hemispheric, regional only (e.g., Europe and N. Atlantic - can then refer back to it in ocean section)? Was it one synchronous warm event or a bunch of shorter regionally asynchronous events? Warmer than 20th? Late 20th? (think you answered this, but need to nail it!). Cite the cast of papers you've already discussed, plus Bradley et al Science 03.
4. what you say is balanced, and it's ok to note in the text where you anticipate serious improvement w/ more published paper support - e.g., Esper (you're doing a paper on this, no?) and ECHO-G.
5. have to have boreholes on Figs too - that would be more important now than uncertainty estimates around all recons - the latter is harder, but in any case, say what you intend to add after ZOD.
6. see text - minor edits
7. I can make draft bullets from what you sent

Guys - it was worth the wait. Hope you can take advantage of the relatively minor edits required and help some with other sections as asked for.

<x-flowed>

Hi Keith -

- 1) ok on the refs - send tomorrow
- 2) glad you're keen for the box - it can't be too long - maybe shot for ca. 400 words? After the ZOD is done, I'm sure we can tune to the correct balance of info. A fig is ok if it's compelling. The box will either be 6.1 or 6.2 depending on whether you refer to it in your section before or after the glacier box. I'm guessing it'll be 6.1 and come first, but it's your call. Think of a title for the box - something like "Box 6.1: The Medieval Warm Period" or maybe something more catchy. Can't be too glib.
- 3) glad you have some borehole in there. Of course, you'll be at the front of the line for dealing with the grief we get no matter what choice we make. So the key is to go with what can be best justified. Your section has this nice balance already.

Thanks for getting Tim (and you as time permits) to work on those other sections - VERY important too. But, your section is the most important.

thx, Peck

From: David Rind <drind@giss.nasa.gov>
To: Stefan Rahmstorf <rahmstorf@pik-potsdam.de>
Subject: Re: 6.5.8 revisions
Date: Thu, 13 Jan 2005 17:00:26 -0500
Cc: David Rind <drind@giss.nasa.gov>, Tim Osborn <t.osborn@uea.ac.uk>, Jonathan Overpeck <jto@u.arizona.edu>, Keith Briffa <k.briffa@uea.ac.uk>, Eystein Jansen <eystein.jansen@geo.uib.no>, FortunatJoos@email.arizona.edu

Here are my responses to Stefan's comments. While I could have made each of these points in the document itself, it is already sufficiently long that Jonathan had me cut it before most of you guys saw it.

At 8:53 PM +0100 1/13/05, Stefan Rahmstorf wrote:

Hi folks,
on the topic of climate sensitivity. I just lost a long mail on it due to a software crash, so sorry if I'm brief now.

I think it makes no sense for the purpose of the IPCC to discuss a climate sensitivity to orbital forcing - if such a thing can be defined at all. The first-order idea of orbital forcing is that in annual global mean it is almost zero - and in any case the large effect orbital forcing has on climate has very little to do with its global mean value. Hence, we'll confuse people by discussing it in this way, and even citing numbers for it. For the purpose of IPCC, I think climate sensitvity should refer to climate sensitivity wrt. greenhouse gases.

The point here is that climate can be forced by other factors than simply a global, annual average radiation change, which is the metric now being used. The orbital forcing induced changes are wonderful examples of this, hence the paleoclimate chapter is a perfect place to discuss it. Variations in seasonal and latitudinal forcing clearly have had a major impact on climate, including forcing of ice ages, yet the annual average radiative change is small. The importance of this with respect to IPCC is that other climate forcings can also affect the seasonal and latitudinal distribution of radiation - aerosols, land surface changes, and even solar radiation (considering cloud cover distributions) - hence they too may have a disproportionate influence compared to their annual global average magnitude.

What is said in this subsection is simply that this one metric clearly fails with respect to the major variations in paleoclimate, and as a general rule, there should be room for an expanded concept (which may then have utility for current and future climate forcing as well).

Also, it is questionable to discuss climate sensitivity for uncoupled models, especially for glacial times - Ganopolski et al. (Nature 1998) have shown that glacial climate looks very different with mixed layer ocean vs. coupled. I think for a 2007 IPCC report we shouldn't be discussing old uncoupled runs when coupled model results are available. (And it is a little odd that the above paper, the first coupled model simulation of glacial climate, cited over 150 times so far, is ignored here in the discussion of the last glacial maximum - if you do a search on the Google Scholar engine for the key words "Last Glacial Maximum", you'll find it's the second-most cited paper on this topic after the Petit et al. Vostok data paper.)

In fact, most if not all of climate sensitivity measurements have been done for what Stefan calls "uncoupled models", atmospheric models coupled to mixed layer ocean models. The results from all prior IPCC reports give sensitivities from precisely these types of models - for the basic reason that almost no one has ever run a coupled model for 2CO2 to equilibrium. The other disadvantage of coupled models in this regard is that their control run, if simulated long enough, often does not reproduce the current climate in important respects - one is then getting a climate sensitivity with respect to something far removed from the current climate, so what good is it? The fact that models coupled to a dynamic ocean and those coupled to mixed layer oceans may get different responses - and one can see from the numbers that the responses are actually fairly similar in general - can be related to the ocean dynamics changes; as the text notes, that is considered a feedback in this subsection, and therefore an appropriate part of the climate sensitivity calculation.

I still think it makes no sense to say that climate sensitivity depends on the sign of

the forcing. Talking about greenhouse gases: whether you will do an experiment going from 280 ppm to 300 ppm, or the other way round from 300 ppm to 280 ppm, should give you the same climate sensitivity. Perhaps you mean that going from 280 to 300 will give a different result compared to going from 280 to 260, but then you're really comparing different mean climates. I think this "directionality" of climate sensitivity is not a good concept.

It's not the forcing per se that's the issue here, it's the feedbacks that potentially can alter the climate sensitivity to the sign of the forcing.

It has been suggested in the past that climate sensitivity is larger to cooling perturbations than to warming ones, and we ourselves have found that result in some earlier model runs. The standard reason given is that with a cooling climate perturbation, sea ice can expand further equatorward, to cover a broader area, and intersect more solar radiation - therefore providing a more positive feedback to the cooling. In a warming climate, the sea ice retreats and intersects less radiation - but the sunlight-weighted area is smaller in the regions it is retreating to, so its positive feedback to the warming is not as large.

However - water vapor works the opposite way. Given the exponential dependence of water vapor on temperature, in a warming climate the added temperature would allow for a greater water vapor change (increase) than would occur with a cooling climate of the same magnitude. Hence the water vapor feedback should be greater in a warming climate.

So the answer is - nobody knows. Jim Hansen did a survey of people at GISS recently to see what the general opinion was for a paper he's working on (and sending around). Since paleoclimates have suffered both positive and negative forcings (in the examples given in this section), and since we don't know the answer to this question, we can't really say whether the sign of the forcing is important or not. So I've left it as an open question, with the possibility that it might matter.

Relating forcing to response, the sensitivity from the models is then on the order of $0.6^{\circ}\text{C}/\text{Wm}^{-2}$ (or higher, depending on the model used); the sensitivity from the observations, if taken at face value, would be considerably less.

I still don't understand how you get this conclusion. This would mean: if you take models with those estimated forcings and run them, they should show a big mismatch with the proxy data. As far as I can tell from the diagram by Mike Mann attached, combining models and data, only the Von Storch simulation (not shown on this one) does show such a mismatch. (And that uses 1.5 times the Lean solar forcing.)

If you look at the various model simulations done for this time period, the only way the models can reproduce the "observed" cooling relative to the present is by using only a subset of the forcings. When you use all the forcings, you get a much higher number. You can do the math yourself: with a "best-guess" radiative forcing change of 2.4Wm^{-2} , models with a sensitivity of $0.6^{\circ}\text{C}/\text{Wm}^{-2}$ will get a temperature change of some 1.5°C , which over the course of 300 years shows up in GCMs. For example: Cubasch et al (1997), using just solar forcing in the ECHAM 3 model came up with cooling of 0.5°C ; if you add a reasonable response to the approximately $1.5\text{--}2\text{ W/m}^2$ forcing from trace gases plus aerosols, you get an additional 1°C cooling (given the sensitivity stated above). Counteracting that could be land surface changes - but counteracting that are undoubtedly the reduced pre-industrial tropospheric ozone, plus any additional volcanic cooling (a la Crowley). So assuming those sort of cancel, we have a 1.5°C cooling for the MM time period from solar plus anthropogenic, similar to what we get in the GISS model (as noted in our 2004 paper). That can be compared with the Mann et al reconstruction - and you can see from your figure that for the 1700 time period relative to the 1990s, the cooling is about 0.5°C . Similarly, Fischer-Bruns et al. (2002) with the ECHAM 4 model, using solar forcing of -0.1% for the MM, and volcanic forcing greater than today (like Crowley) got a cooling of 1.2°C . The Zorita et al study also got a large magnitude cooling when using all the forcings. BTW, neither ECHAM 3 nor ECHAM 4 has a large climate sensitivity - it is of the order of

0.6C/Wm-2, as referred to in the comment above. Note that none of these models are shown in your accompanying figure, and all are GCM studies.

How did the Crowley and Bauer studies that are shown in the figure (using EB or EMIC models) get the smaller cooling magnitudes indicated there? Only by using a subset of the forcings - Crowley basically threw out the solar changes (and had a lower sensitivity model), Bauer et al. used a large aerosol effect and still needed a large deforestation warming to bring her results in line with the Mann et al. reconstruction (in fact, it was done specifically for that reason). None of these runs used the tropospheric ozone reduction that we have evidence did occur. My impression is that these studies took the observations as given and were asking the question of what forcings would be needed to reproduce them. That is an interesting question, but it obviously does not validate the observations.

The specific comment you refer to above relates to the discussion in the previous paragraphs, which detail the radiative forcings and all the different model responses. It is a fair representation of the current status, however unsettling that is. But in the current incarnation of this subsection, we do not use it to imply a low climate sensitivity - we simply say that given the uncertainties in forcing and response, we cannot use this time period to better understand climate sensitivity. And I think that's accurate.

David

Subject: near final 6.3.2.1

Date: Thu Jan 13 19:03:36 2005

Guys

here is the latest draft of 6.3.2.1 (only waiting on slight edits on ocean bit from Eystein and ENDNOTE reffs to be sorted. Have agreed with Peck and Eystein to do a Medieval Warm Box tomorrow and insert a sentence or two on lack of info for SH .Figures of course need work -

particularly sorting out how to represent uncertainty around all reconstructions in Fig 1 and represent totality ion Fig 2d. Also some forcing data still missing - may have to wait til after ZOD (will also need to put in other borehole curve(s) but data not to hand).

Having virus troubles with by email (and our system randomly blocking some files) - sorry so don't know whether David has seen this at all (re his comments on Figures - which are now embedded as GIFs and attached separately as 2 files in case go wrong again.

As I type just got Stefan's message and comments and Goose paper- will look at tonight and incorporate tomorrow.

David - I know it is received wisdom that volcanos only force climate for 1 to 2 years - but in our SOAP transient models this is not the case where several large eruptions occur (co- incidentally often in sunspot minima periods - see the actual magnitude of radiative forcing in Figure 2 (and these effects are directly transmitted as continually propagating coolings in ocean in HADCM3 and ECHO-G for up to decades i believe. Anyway - I am happy with your conclusions and agree that these are not "negative". I would rather just pick a cool period and not label it as MM (or late MM) as this is a solar definition as such should be defined according to solar proxy data (and hence choice of shorter period seems unsupported). If you just say a date range without the label , I think it avoids the issue.

Sorry for garbled writing but rushing - I like your bit (in case this did not come across) thanks all for now

<x-flowed>

Dear Keith,

you've done a great job on the touchy subject of the last millennium, which is central to our whole chapter.

My comments to that are threefold:

(1) If you could shorten the text somewhat, it could become more powerful

(2) Some small edits & comments are in the attached doc

(3) I propose some improvements to the figures as follows.

- Fig 1a the land temps seem to go off plot, temperature scale needs to be extended

- we need a break between panels a and the rest, since it's a different time scale on the x axis

- Fig 1c also has one curve going off the top

- Panels 1b-d might run the time axis up to 2010 or so, else the important rise at the end is hidden in the tick-marks and less obvious than it should be

- the legends need to say what the baseline period (zero line of y-axis) is (hard to find this in the axis label)

- this baseline should be the same for all curves, i.e. 1961-1990. Fig 2d says 1901-1960 - it's not ideal to have a different one, as compared to Fig 1. Also, is it true? Surely the Storch curve is not shown relative to this baseline, it's way above it. Aligning it like this could lead to the dangerous misunderstanding that Storch suggests a much warmer medieval time compared to everyone else, which of course is not the case.

I hope this helps.

Cheers, Stefan

Hi friends,

good idea for a box. Just want to make sure you're aware of the attached paper by Goosse et al., which may be helpful in illustrating what we all know, but what here is shown in a citeable way: local climate variations are dominated by internal variability (redistribution of heat), only very large scale averages can be expected to reflect the global forcings (GHG, solar) over the past millennium.

Hi folks,
on the topic of climate sensitivity. I just lost a long mail on it due
to a software crash,
so sorry if I'm brief now.

I think it makes no sense for the purpose of the IPCC to discuss a
climate sensitivity to
orbital forcing - if such a thing can be defined at all. The first-
order idea of orbital
forcing is that in annual global mean it is almost zero - and in any
case the large effect
orbital forcing has on climate has very little to do with its global
mean value. Hence,
we'll confuse people by discussing it in this way, and even citing
numbers for it. For the
purpose of IPCC, I think climate sensitivity should refer to climate
sensitivity wrt.
greenhouse gases.

Also, it is questionable to discuss climate sensitivity for uncoupled
models, especially
for glacial times - Ganopolski et al. (Nature 1998) have shown that
glacial climate looks
very different with mixed layer ocean vs. coupled. I think for a 2007
IPCC report we
shouldn't be discussing old uncoupled runs when coupled model results
are available. (And
it is a little odd that the above paper, the first coupled model
simulation of glacial
climate, cited over 150 times so far, is ignored here in the
discussion of the last glacial
maximum - if you do a search on the Google Scholar engine for the key
words "Last Glacial
Maximum", you'll find it's the second-most cited paper on this topic
after the Petit et al.
Vostok data paper.)

I still think it makes no sense to say that climate sensitivity
depends on the sign of the
forcing. Talking about greenhouse gases: whether you will do an
experiment going from 280
ppm to 300 ppm, or the other way round from 300 ppm to 280 ppm, should
give you the same
climate sensitivity. Perhaps you mean that going from 280 to 300 will
give a different
result compared to going from 280 to 260, but then you're really
comparing different mean
climates. I think this "directionality" of climate sensitivity is not
a good concept.

Relating forcing to response, the sensitivity from the models is then on the order of $0.6 \text{ }^{\circ}\text{C} / \text{Wm}^{-2}$ (or higher, depending on the model used); the sensitivity from the observations, if taken at face value, would be considerably less.

I still don't understand how you get this conclusion. This would mean: if you take models with those estimated forcings and run them, they should show a big mismatch with the proxy data. As far as I can tell from the diagram by Mike Mann attached, combining models and data, only the Von Storch simulation (not shown on this one) does show such a mismatch.

(And that uses 1.5 times the Lean solar forcing.)

Subject: the new "warm period myths" box

Date: Thu, 13 Jan 2005 21:45:38 -0700

Cc: Eystein Jansen <eystein.jansen@geo.uib.no>, Valerie Masson-Delmotte <Valerie.Masson@cea.fr>

<x-flowed>

Hi Keith and Tim - since you're off the 6.2.2 hook until Eystein hangs you back up on it, you have more time to focus on that new Box. In reading Valerie's Holocene section, I get the sense that I'm not the only one who would like to deal a mortal blow to the misuse of supposed warm period terms and myths in the literature. The sceptics and uninformed love to cite these periods as natural analogs for current warming too - pure rubbish.

So, pls DO try hard to follow up on my advice provided in previous email. No need to go into details on any but the MWP, but good to mention the others in the same dismissive effort. "Holocene Thermal Maximum" is another one that should only be used with care, and with the explicit knowledge that it was a time-transgressive event totally unlike the recent global warming.

Thanks for doing this on - if you have a cool figure idea, include it.

Best, peck

Hi David,
thanks for the detailed response. I'll try to be brief.
On the orbital forcing you write:

The point here is that climate can be forced by other factors than simply a global, annual average radiation change, which is the metric now being used.

I think we all agree on this point. My concern is only about how to present it in the section. I think that giving a climate sensitivity wrt. global mean orbital forcing is confusing to the uninitiated, e.g. your statement in the section:

This high climate sensitivity ($2\text{C}/\text{Wm}^{-2}$) is occurring in an atmospheric model (ECHAM-1) whose sensitivity to doubled CO_2 is about $0.6\text{C}/\text{Wm}^{-2}$.

I really think we should not give a number like $2\text{C}/\text{Wm}^{-2}$ as "climate sensitivity" to global-mean orbital forcing and contrast it to that to doubled CO_2 . It gives out the message to people that climate sensitivity is all over the place and ill defined. That's not the case. Climate sensitivity is a well-defined concept for a globally uniform forcing like CO_2 forcing, but nobody expects any clear relation between the global mean part of orbital forcing and the climate response.

On uncoupled models:
I agree that for $2\times\text{CO}_2$ runs, you will get very similar climate sensitivity with uncoupled and coupled models, because there is no large change in ocean heat transport between equilibrium $1\times$ and $2\times$ CO_2 states (as confirmed by doing this in coupled models). The mixed layer boundary condition used in the uncoupled models simply assumes a fixed, prescribed ocean heat transport, which turns out to be a valid approximation in this case.

My concern was and is specific to the discussion for LGM climate, where this is not a valid approximation, as we know both from proxy data and from model results that ocean circulation and heat transport was very likely quite different in the LGM compared to

today. In our Nature 98 LGM simulation, we get 50% difference in the response of the

Northern Hemisphere mean temperature, between the uncoupled "mixed layer" experiment and

the one that includes the ocean model. 50% is a first-order difference, and hence I think

that all the evidence we have today, points to the "constant heat transport" approximation

breaking down when applied to the LGM. The IPCC report should not draw conclusions about

climate sensitivity from LGM experiments that have made this approximation, as I think

those would be hard to defend. I must say I'm starting to get a little concerned about the

chapter discussing 1980s papers for no other apparent reason than them being authored by

Rind, while leaving out important more recent, widely recognised advances in the field.

I attach the Schneider et al. paper I announced earlier, submitted to Science today and

arguable the most comprehensive study on deriving climate sensitivity from LGM data

constraints that has been done so far.

On the directionality of the climate sensitivity:

of course I understand the reasons, the ice feedback and water vapor feedback etc., I've

written about those myself in the past - again this is only a difference in how best to

present the same, undisputed facts. You make the argument that when going to a colder

climate, sensitivity is different from when going to a warmer climate. That is undisputed.

But that in my view has nothing to do with the "direction" of the experiment, but with the

fact that sensitivity in a colder climate is different from sensitivity in a warmer

climate. I explained with the ppm example because I thought that's simple. A

"directionality" would be, if going from 280 to 300 ppm would give a different equilibrium

response compared to going from 300 to 280. But that's not what you're talking about. Your

talking about going from 280 to 260 (say), as compared to going from 280 to 300. That of

course gives different results, because the difference 280-260 applies to a colder climate

than the difference 300-280 (no matter in which "direction" you derive this).

From: David Rind <drind@giss.nasa.gov>
To: Stefan Rahmstorf <rahmstorf@pik-potsdam.de>
Subject: Re: 6.5.8 on climate sensitivity and last millennium
Date: Fri, 14 Jan 2005 14:23:47 -0500
Cc: David Rind <drind@giss.nasa.gov>, Tim Osborn <t.osborn@uea.ac.uk>, Jonathan Overpeck <jto@u.arizona.edu>, Keith Briffa <k.briffa@uea.ac.uk>, Eystein Jansen <eystein.jansen@geo.uib.no>, Fortunat Joos@email.arizona.edu

Here are my responses to the comments concerning 6.5.8d. With respect to Stefan's main concern: I too am sensitive to the possible mis-use of words that appear in a cavalier manner in the text. I think the way to avoid that is to be as precise as possible about what is being said. I also feel that hand-waving should be minimized - just because there are uncertainties, does not mean IPCC will throw up its hands. Thus the attempt to quantify these numbers are precisely as they will be done in other IPCC chapters. Again, the responses are in red, and the text alterations (or in this case, some entire text) are in blue.

I'm not working on this topic myself so I'm by no means an expert. But I am still quite concerned with the wording in 6.5.8 on the last millennium. First, to avoid misunderstandings, I would like to suggest again to describe forcings and climate changes going forward in time, rather than going backwards in time. Even colleagues here that I discuss it with misunderstand the present version with backwards reasoning - it leads to phrases like "deforestation warming" (used by David in his last mail), although deforestation caused cooling - backwards in time you can see this as a warming, but should you call it "afforestation warming" if you look back in time? I suggest to use the physical, forwards, time arrow in the discussion.

In all the other sections of 6.5.8 we discuss the temperature change and the radiative forcing relative to the present - when it was colder than the present, the temperatures were indicated to be colder, and the radiative forcing more negative. To alter that for this section alone would cause added confusion. I have therefore in each case tried to make it perfectly clear what is being said. In particular, I agree that in the case of deforestation the terminology does become confusing so the text has been changed to be more

communicative; it now reads,

Warming of 0.35°C due to the existence of vegetation and forests that have since been cut down was found by (Bauer et al., 2003) ...

The section states:

If one takes mid-range estimates of solar and anthropogenic forcings, and assumes that volcanic, tropospheric ozone and land albedo changes cancel out, the resulting radiative forcing change is $\sim -2.4 \text{ Wm}^{-2}$.

I don't think we should give a "mid-range" of the forcing like this; the assumption that ozone, land albedo and volcanic changes cancel is hard to justify in any case. For the forcing we need to give a range in my opinion, not one number. If we give a range, it will become clear that the forcing is too uncertain for drawing conclusions on climate sensitivity from this time period.

The problem with giving a maximum range for this time period is the same as giving one for the 20th century - the inclusion of the potential indirect effects of aerosols means you can wipe out all climate forcing entirely. It becomes a 'reductio ad absurdum'. The issue in particular for the Late Maunder Minimum time period, and the specific reason for including it, is that it potentially says something about SOLAR forcing.

In writing this section, we are not simply doing a core dump of everything people have done, we are supposed to use our brains to assess the likely situation. Having already provided the range of uncertainty, we can give a 'best estimate' for the various forcings that we can use in a meaningful way if we are careful - and which show the importance of the uncertainty in the solar forcing. I do agree that what existed in the text especially for the third paragraph needed improvement. Therefore, after several talks with people here, I've altered (especially) the first and third paragraphs accordingly. Rather than just stating the conclusion that climate sensitivity can't be well defined, the paragraphs now show quantitatively that is the case. The specificity, I believe, gives people a real

feeling for the uncertainties, and in the way it is done here, especially the uncertainty in the solar forcing and actual climate response. (This rewrite obviates the need for a direct response to several of Stefan's other comments.)

(d) Last 1000 years

We concentrate here on the Late Maunder Minimum time period in which sunspots were generally missing (approximately 1675-1715), but outside of the estimated solar irradiance change, the discussion is applicable for the pre-industrial climate in general. The primary forcings relative to today are (1) a decrease in various greenhouse gases, with a forcing of approximately $-2.4 \pm 0.25 \text{ Wm}^{-2}$ (not including tropospheric ozone changes); (2) reduced tropospheric sulfate aerosols, whose direct effect is estimated by IPCC (2001) as $+0.4 \pm 0.3 \text{ Wm}^{-2}$ with an indirect effect ranging from $+0.5$ to $+2 \text{ Wm}^{-2}$ (3) a solar forcing reduction estimated as ranging from -0.12 to -1.56 Wm^{-2} (0.05% to 0.65%) ((Hoyt and Schatten, 1993); (Lean, 2000); (Foukal and Milano, 2001); (Reid, 1997)); and (4) volcanic aerosol forcing either similar to today ((Robertson, 2001)), lower than today ((Robock and Free, 1996)), or higher ((Crowley, 2000)). Large uncertainties therefore exist for all of the forcings except the trace gas values (again excluding tropospheric ozone). The cooling effects are offset to small degree by land albedo changes, estimated to contribute $+0.4 \text{ Wm}^{-2}$ ((Hansen et al., 1998)). Reduced tropospheric ozone has been estimated to cause an additional forcing of -0.3 to -0.8 Wm^{-2} (Mickley et al., 2001), while increased stratospheric ozone produced a positive forcing of -0.09 to -0.25 Wm^{-2} (IPCC, 2001). If one takes the most widely used or mid-range estimates of solar (-0.5 Wm^{-2} from (Lean, 2000)) and anthropogenic forcings (-2.4 Wm^{-2} from reduced trace gases, other than tropospheric ozone; $+0.5 \text{ Wm}^{-2}$ from reduced sulfate aerosols), land albedo changes (0.4 Wm^{-2}), decreased tropospheric ozone (-0.35 Wm^{-2} (IPCC, 2001)) and increased stratospheric ozone ($+0.15 \text{ Wm}^{-2}$ (IPCC, 2001)), the net radiative forcing for this time is estimated as -2.2 Wm^{-2} . [For this exercise we ignore the effects of volcanoes, the indirect effects of sulfate aerosols, and the effects of carbon and organic aerosols.]. Including these additional components (except

for volcanic aerosols for which even the sign of the change is not well known), Hansen (personal communication) calculates a value close to -2 Wm^{-2} . How cold was this time period? Different reconstructions (Fig. X1) provide different estimates of cooling, ranging from -0.45°C ((Mann et al., 1999), annual value for the Northern Hemisphere), to about -0.7°C ((Esper et al., 2002) for 20-90°N in the growing season, and (Briffa and Osborne, 2002) (from borehole temperature records). Model studies (Fig. X2) for this time period have generally employed significant solar reductions (-0.2% to -0.4%), which by themselves have resulted in cooling of about -0.5°C ((Cubasch et al., 1997); (Bauer et al., 2003); (Rind et al., 2004)). Utilizing a forcing of -1.5 to -2 Wm^{-2} from the combined influence of preindustrial trace gases and aerosols results in additional cooling of about -1 to -1.5°C ((Fischer-Bruns et al., 2002); (Rind et al., 2004); (Zorita et al., 2004)). If volcanic aerosols were actually more extensive during this time period, then additional cooling would arise from this factor as well (on the order of -0.4°C found by (Hegerl et al., 2003) using the (Crowley, 2000) reconstruction). Warming of 0.35°C due to the existence of vegetation and forests that have since been cut down was found by (Bauer et al., 2003), on the same order but of opposite sign to the tropospheric ozone forcing (Mickley et al., 2004). Adding these effects from model simulations together produces a total cooling on the order of -1 to -1.5°C or greater, significantly larger than any of the paleo-estimates. For the ~ 50 year time period associated with the Maunder Minimum, without large forcing trends, the model results are essentially in radiative balance, and while the influence of past solar variations could still be in acting, in at least one study they were shown to be unimportant (Rind et al., 2004).

The climate sensitivity from the GCMs used for these studies is on the order of $0.6^\circ\text{C}/\text{Wm}^{-2}$ (or higher, depending on the model used). To calculate the sensitivity from the observations, we first use the estimated forcing of -2.2 Wm^{-2} and recognize that $\sim 0.85 \text{ Wm}^{-2}$ of this is unresolved (Hansen, personal communication) due to the rapid trace gas changes of the last few decades. Therefore, only 1.35 Wm^{-2} of the radiative forcing should have

been expressed in the system. Were this to have resulted in a temperature change of about -0.5°C (as in the Mann et al reconstruction), it would imply a climate sensitivity of 0.37 Wm^{-2} , i.e. at the low end of the IPCC range for doubled CO_2 response. Using the higher estimated cooling of -0.7°C results in a climate sensitivity of 0.52 Wm^{-2} . Alternatively, if the uncertain solar forcing change was at the estimated minimal value (-0.12 Wm^{-2}), then the radiative forcing change would be reduced accordingly, and climate sensitivity for the two reconstructions increases to 0.5 Wm^{-2} and 0.7 Wm^{-2} (near 3°C for doubled CO_2) respectively, for the different temperature reconstructions. This exercise can be carried on ad infinitum; considering the actual uncertainty in many of the forcings, and in the actual temperature response of the climate system, we conclude that we cannot properly constrain climate sensitivity for this time period (and to some extent the results are similar for other preindustrial time periods compared to the present).

As an aside: if one uses the minimal estimate of solar forcing in the example presented, one gets a range of temperature response to $2\times\text{CO}_2$ of $2-3^{\circ}\text{C}$, not too much different from that concluded in the paper Stefan just sent around (which was 2.5 to 3°C).

Then you state the Mann et al. data are 0.5°C below the 1990s in the Maunder Minimum. I can see they are 0.4°C below the reference level (I believe this is 1961-1990). The mean of the 1990s is 0.3°C above this level (I calculated this from the Jones data) - so I find that the Mann data are in fact 0.7°C below the 1990s in the MM. The difference between model expectation for 2.4 W/m^2 and the actual found in the Mann data is almost gone then. Add to that the possibility that the Mann data may somewhat underestimate the variability, and I do not see any significant discrepancy between models and data, which we should mention and which we could defend as real - even for "best guess" sensitivity and forcing, let alone considering the uncertainty in those.

The easiest way to see this is to note that the Mann et al reconstruction has the late 1600s slightly warmer than the late 1800s. It is widely acknowledged that the late 1800s

were 0.6C colder than today (taking into account the heat island effect) (and the radiative forcings, a la IPCC 2001, are all with respect to the 1990s.) That puts the late 1600s at less than 0.6C colder, close to the value indicated in the text.

David

Hi Mike - of course we shouldn't make that assumption. If the issues are being dealt with elsewhere in the peer-reviewed literature soon (in time for IPCC to be aware of them) then there would be no reason for a riposte in GRL. Even so, it might be worth putting the hypothetical case to the Editor-in-Chief to test his response. Cheers, Malcolm

Tom,

I'll look at what you've said over the weekend re CCSP.

I don't know the other panel members. I've not heard any more about it since agreeing a week ago.

As for FOIA Sarah isn't technically employed by UEA and she will likely be paid by Manchester Metropolitan University.

I wouldn't worry about the code. If FOIA does ever get used by anyone, there is also IPR to consider as well.

Data is covered by all the agreements we sign with people, so I will be hiding behind them. I'll be passing any requests onto the person at UEA who has been given a post to deal with them.

Cheers

Phil

At 14:35 21/01/2005, Tom Wigley wrote:

Phil,

Thanks for the quick reply.

The leaflet appeared so general, but it was prepared by UEA so they may have simplified things. From their wording, computer code would be covered by the FOIA. My concern was if Sarah is/was still employed by UEA. I guess she could claim that she had only written one tenth of the code and release every tenth line.

Sorry I won't see you, but I will not come up to Norwich until Monday.

Let me fill you in a bit (confidentially). You probably know the panel members. We were concerned that the chair would be a strong person. It is Jerry Mahlman -- about the best possible choice. Richard Smith is the statistician -- also excellent. Dave Randall, too -- very good. As token skeptic there is Dick Lindzen -- but at least he is a smart guy and he does listen. He may raise his paper with Gianitsis that purports to show low climate sensitivity from volcanoes. I will attach our paper that proves otherwise, in press in JGR.

Preparing the report has been a good and bad experience. I think I had the worst task with the Exec. Summ. -- it tied up most of my time for the past 3 months. The good has been the positive

interactions between most of the people -- a really excellent bunch. I have been very impressed by Carl Mears and John Lanzante. At meetings, John Christy has been quite good -- and there were good and positive interactions between John and Roy and the RSS gang that helped clarify a lot. Outside the meeting, in the email world, he has been more of a pain. He has made a lot of useful suggestions for the ExSumm -- but he keeps accusing the AOGCMers of faking their models (not quite as bluntly as this). In the emails there are some very useful exchanges from Jerry Meehl, Ramaswamy and Ben detailing the AOGCM development process. We will be writing a BAMS article on this in the summer -- much of what happens in model development is unknown to the rest of the community. The 'faking' idea prompted me to write a tongue in cheek note -- also attached. As far as I know, John will not raise this particular issue in his dissentin views.

To accommodate dissenting views, the report will have a "dissenters' appendix", with responses. You will get this at some stage -- the deadline for dissenters to produce is Jan 31, and we will not finish our rebuttals until mid Feb. The dissenters are John C, and (far worse) Roger Pielke Sr. All of the rest of us disagree with these persons' dissenting views. Roger has been extremely difficult -- but the details are too complex to put in an email. On the other hand he has made a number of useful contributions to the ExSumm and other chapters. Suffice to say that he has some strange ideas (often to do with the effects of landuse change) that are interesting but still, in my view, speculative -- but testable.

We have yet to see the dissents -- and it would not be ethical for me to say any more than I have already.

Best wishes,

Tom.

Phil Jones wrote:

Tom,

I hope the VTT panel doesn't prove a meeting too many at this time. It is currently scheduled for Feb 23-25 and I only get back from an 8 day workshop in Pune on Feb 20.

The IPCC Chapter with Kevin is now with WGI in Boulder. We did put you down as one of our potential reviewers. Don't know whether you'll have time or whether WGI will select you - regional balance etc.

Next week I'll be in Reading and Exeter, so

won't be in CRU. Have to be at an RMS Awards meeting then something on Reanalysis, then I have to collect some data from the archives in Exeter for a small project we have. It is easier for me to get this than explain to someone how to do it. So I'll miss you - not back till Thursday night.

On the FOI Act there is a little leaflet we have all been sent. It doesn't really clarify what we might have to do re programs or data. Like all things in Britain we will only find out when the first person or organization asks. I wouldn't tell anybody about the FOI Act in Britain. I don't think UEA really knows what's involved.

As you're no longer an employee I would use this argument if anything comes along. I think it is supposed to mainly apply to issues of personal information - references for jobs etc.

Sorry I'll miss you next week. If you're in on Sunday perhaps you could come round to our new house in Wicklewood. Phone number is still the same as 01953 605643. Keith and Sarah know where it is even if they did get lost the first time they came.

Cheers

Phil

At 02:59 21/01/2005, you wrote:

Phil,
Tom Karl told me you will be on the VTT review panel. This is very good news.

Unfortunately I will not be at the meeting on the 23rd -- I will be in midair half way across the Pacific to spend a couple of weeks in Adelaide.

I got a brochure on the FOI Act from UEA. Does this mean that, if someone asks for a computer program we have to give it out?? Can you check this for me (and Sarah).

I will be at CRU next Mon, Tue, Wed in case Sarah did not tell you.

Thanks,

Tom.

Keith,

It is purely a matter of resources, and since Simon will be doing the millennial stuff with the Hadley model within IMPRINT, and I think that probably my resources will be best focussed in some of the other work packages. But it is possible and I will try to do it if the opportunity arises.

Cheers

Paul

Hi Eystein

I received these comments below from our research office. This outlines the Newcastle approach.

In one case at least it is clear that the idea that groups would not join another consortium as agreed by the ssc had not been passed on to partners outside those discussions. To apply this retrospectively could be seen as unfair - this is obviously how Millennium interpret it. One option that would avoid a split and limit any wider damage or bad feeling would be to get partners to sign a confidentiality agreement now. This would restrict or stop the flow of information between consortia, which, after all, is the main cause for concern.

Cheers, Steve

Sent: 28 January 2005 11:40
To: Tony Stevenson
Subject: RE: Question on ethics

Sharp practice certainly. Not necessarily unethical I would have thought.

In a number of cases we have been asked by coordinators to sign up to an exclusivity agreement whereby we will not take part in other consortia who are applying under the same call.

However, we have resisted this saying that we cannot restrict the activities of other academics on the campus, although we have been prepared to sign up to such an agreement that would limit the activities of the particular PI and his/her immediate research group. That way, all of those involved are fully aware of the commitment and its implications. Of course, if they are not happy about this we would not sign up but that in turn would probably mean exclusion from the consortium.

Additionally, and this applies to any collaboration during the preparatory stage, we would recommend that a confidentiality agreement were put in place; this at least would limit the onward transmission of information that could help another grouping.

In this instance I guess that we are where we are.

As it was not established at the outset that a party could only be

involved with one group it may be difficult to move to that position now, not so much because of issues with the other Coordinator but more importantly because it could jeopardise ongoing relationships with fellow collaborators who would be made to choose sides. There again, as these are the probably the very parties who have operated as split personalities there is the question of working with them again.

In any event, it may still be sensible to try to implement a confidentiality agreement so that access to information is restricted and not used to help the other consortium's cause.

Of course, there is the other option of possibly joining forces. The result could be an even stronger application.

Dear Dirk

good news re your not dropping out . We are happy to have you and if you can do what you can in the time available this would be good. Valerie and I will send a general message Monday am to all WP1 folk to say what is needed now, but we thought it best to get back to you straight away re specific points raised in Steve's message.

First, I hope you will be responsible with Dan (and help from Sandy Tudhope) for co-ordinating Task 1.4 of WP1 following the concept as we saw it in the preliminary proposal. Of course you would focus on North African (and north and south of this area) work - on the collection, comparison, integration, interpretation of the high and lower resolution records that relate to hydrology. I see Dan as taking the strain regarding the more Northern areas - with obvious attention to wetlands and Sandy helping with dynamic links (and ENSO?). Of course there are other records and there will be a need to restrict "new" collection/laboratory analyses to very specific , justified (and accepted by SC) situations , but the high resolution core(s) you told me of would be relevant. I suggest you think in terms of a person to work on this AND data compilation - perhaps a (cheap) postdoc for 3 years , and money for internal WP1 meetings - say 250KEuro ?

FOR NOW - we need you to liaise with Dan and Sandy to produce what you can for the Task 1.4(see attached old version of proposal to start from) . We will need a "state of the Art" Scientific objectives and approach details . Your whole Task 1.4 section can only be 1 page A4 single spaced max.

AFTER LONG DISCUSSION IN LONDON- it was decided that this task would NOW NOT INCLUDE the paleoflood work - and Eystein will be communicating with Bennitto to (regretfully) to inform him that we have had to remove his contribution (please do not contact him until Eystein has done this). We will not put a specific focus on floods (though of course some work can be done using existing European flood data), because of Rudolf Brazdil , and we hope , he will accept to be part of WP1 but put some of his requested funds into WP6 . Hence you 3 can concentrate more on the concept of large scale hydrologic variability ,monsoon changes , north south linkages etc. The problem with ENSO persists. I know you Sandy want to focus entirely on this, but we could compromise perhaps and you do part this and part Europe? It was decided that we will (somewhere) include data/model comparison with US droughts , but this does not require effort on our part other than minor data compilation of existing records [Eystein, we therefore need to ensure Cook is one of the associated americans]. We will put together an appendix of preliminary records to be used in each task - just to show impressive new potential integration (but not a priority for now).

You do not need to sign any forms officially at this stage - just get approval presumably from your department internally . If we ever get there, forms will be handled at contract negotiation.

So get in touch with each other (resend ideas , do not assume your previous emails went to each other), get exchanging ideas and draft what you can .

ON monday , the specific letter to all people will come round , with requested timeline , task, deliverables re budget and precise format of Science writing that we need to assemble the proposal. Then Valerie and I will have to look at the whole thing in the context of our total 3.7 M budget.

IT WILL ALL SEEM WORTH IT IN 2006

All the very best Keith and Valerie

Hi Keith, copy to Eystein, Oyvind

Just had a long chat with Dirk. It's OK, he's not in Millenium!

The reason he was pulling out is over committment this year. Anyway, I managed to persuade him to change his mind - the project won't start until Jan 2006 at the very earliest, so any input won't be needed until next year. He was also unsure what to ask for - I suggested he should cost in a post-doc for 3 years and 2 meetings per year, plus some "data workshops". Keith - can you give him some guidance on costing these so they are in line with what others are asking for. I told him that you would look at the overall budges for WP1 and adjust if necessary to meet the target.

His only short term problem is revising any text for the proposal - he leaves for Kenya next Thursday. I realised that Eystein has only sent the documents to the ssc people so Keith, can you forward these to Dirk and let him know exactly what you need from him for the text and budgets.

Finally, Dirk was worried that he wouldn't be able to get any paperwork & signatures from his Uni but as I understood from the meeting yesterday this was not needed. Is this right? If there are any forms to fill in we had better get these to him asap.

Cheers, Steve

Hi, just for clarification as we continue on the St.2 proposal (you'll get the mailing tomorrow with documents, scheduling etc. as planned). The merger of ICON into Imprint was discussed several times in the preparatory phase of Imprint (before name was decided) in meetings we had in London early last year. However a number of the present WP leaders did not take part in these early deliberations, hence this is the reason for the lack of a collective memory of the background.

Reasons for including it:

1. Good science, on a topic of high relevance (abrupt climate change) focussed and with emphasis on aspects dealing with predictability of such changes rather than mapping out their distribution and impact (as has been done before).
3. Important to avoid competing proposals within Europe to avoid the paleo-community being marginalised.

Cheers,
Eystein

Mike,

It would be good to produce future series with and without the long instrumental series and maybe the documentary ones as well. The long measurements can then be used to validate the low-freq aspects at least back to 1750, maybe earlier with the documentary. There are some key warm decades (1730s, some in the 16th century) which the Moberg reconstruction completely misses and gives the impression that all years are cold between 1500 and 1750.

Away Feb 6-10 and 12-20 and 22-25 (last in Chicago - on the panel to consider the vertical temp work of CCSP).

Cheers

Phil

Cheers

Phil

At 15:26 02/02/2005, you wrote:

Thanks Phil,

Yes, we've learned our lesson about FTP. We're going to be very careful in the future what gets put there. Scott really screwed up big time when he established that directory so that Tim could access the data.

Yeah, there is a freedom of information act in the U.S., and the contrarians are going to try to use it for all its worth. But there are also intellectual property rights issues, so it isn't clear how these sorts of things will play out ultimately in the U.S.

I saw the paleo draft (actually I saw an early version, and sent Keith some minor comments). It looks very good at present--will be interesting to see how they deal w/ the contrarian criticisms--there will be many. I'm hoping they'll stand firm (I believe they will--I think the chapter has the right sort of personalities for that)...

Will keep you updated on stuff...

talk to you later,

mike

Mike,

I presume congratulations are in order - so congrats etc !
Just sent loads of station data to Scott. Make sure he documents everything better this time ! And don't leave stuff lying around on ftp sites - you never know who is trawling

them. The two MMs have been after the CRU station data for years. If they ever hear there

is a Freedom of Information Act now in the UK, I think I'll delete the file rather than send

to anyone. Does your similar act in the US force you to respond to enquiries within 20 days? - our does ! The UK works on precedents, so the first request will test it.

We also

have a data protection act, which I will hide behind. Tom Wigley has sent me a worried email when he heard about it - thought people could ask him for his model code. He has retired officially from UEA so he can hide behind that. IPR should be relevant here,

but I can see me getting into an argument with someone at UEA who'll say we must adhere to it !

Are you planning a complete reworking of your paleo series? Like to be involved if you are.

Had a quick look at Ch 6 on paleo of AR4. The MWP side bar references Briffa, Bradley, Mann, Jones, Crowley, Hughes, Diaz - oh and Lamb ! Looks OK, but I can't see it getting past all the stages in its present form. MM and SB get dismissed. All the right

emphasis is there, but the wording on occasions will be crucial. I expect this to be the

main contentious issue in AR4. I expect (hope) that the MSU one will fade away. It seems

the more the CCSP (the thing Tom Karl is organizing) looks into Christy and Spencer's series, the more problems/issues they are finding. I might be on the NRC review panel, so will keep you informed.

Rob van Dorland is an LA on the Radiative Forcing chapter, so he's a paleo expert by GRL standards.

Cheers

Phil

Kevin,

I was concerned about splitting too, and suggested as a way of getting through the work a little quicker. Pairs will also work as long as we choose the right ones. Agree we need to separate the major from minor, so anything that can be done there in April will be good.

I suspect the comments from the nominated reviewers will all have to answered in a formal way - as a dry run for the FOD and SOD.

On the figures we need to compare notes on these in a few weeks and assign particular people to them. We both worked with Dave on the set of trends. They may not be perfect, but they are better than some of the others. I think we will need to do more of this.

Giving responsibility for a handful to some of the LAs is a possibility. We'll need to give clear instructions though and expect loads of iterations. I can deal with 3.2 with David and the HC if we can agree on what and how we want them. Most of the other sections require much more thought. I'll work on this.

I agree 100% with you on the TC section. This will get scrutinized by many more now. I'll report back on the CCSP review. Apart from Lindzen the panel seem pretty good. So, I'll gauge what the key issues appear to be in the panel's minds. Agree that we shouldn't treat it's conclusions as gospel (otherwise why are we bothering), but treat it as a very very major review article.

Must go home now. Have a good trip back to NZ.

Cheers

Phil

Hi Phil

Not sure how to handle all this. Recall how it was done for GCOS: I don't think that worked. The official version requires each comment to have name etc on it so it can be carved up. The CAs won't do that, so I think we have to treat each CA separately, or at best broken up by section. I can try to get my admin to work on it if we have clear guidelines.

I am also concerned about splitting: There are a lot of things that can be done by LAs working in pairs. In previous IPCCs we broke up into sections. Two people worked on each section in parallel. Lots of things can be done that way. But there are some major things that we have to build a consensus on of all of us. I now have a particular interest in making sure the hurricanes are done well. I also am concerned about the UA-MSU etc and clearly you and I should both be engaged there. So sorting out the fairly minor from major points will be a key task.

I am not taken by our set of figures. If I look at them and try to create a story e.g. by ppt, I think they are lacking. I am attaching the ones I have assembled.

I am away next week in Hawaii at the Chapman conference (AGU). Then I am briefly back and then I am gone and out of touch in New Zealand on personal time 20 Feb to 3 March.

Kevin

Phil Jones wrote:

Kevin,

At least two of the CAs have already begun reading the ZOD. I hope your clear message is followed by all the CAs. Glad you sent the pdf and not the doc version. Tracked changes would be a nightmare.

With all these comments, I presume we'll both assemble all the CA comments. WGI will get comments from our nominated (and their) referee's. I presume WGI will somehow collate these, so for example, all comments on section 3.7 or 3.7.1 will be together.

Is

there a way we can collate all the CA comments similarly? I guess we can decide this later when some more have come in. I reckon we'll have to split the group in Beijing

if we are to get through all the comments in the 3.5 days, so separating them would prove useful. Would an email to WGI be useful to see if they can do it for us? Just a thought !

As you saw, I've reminded our LAs with responsibility for linking with other chapters look at that chapter as well.

No chance so far to look at the CCSP (vertical temp trends) - 6 sections each of 40-70 pages !!

Away from today Feb 6-10 in Madrid (EU project meeting) , 12-20 in Pune (extremes workshop - the last one in the current round, for South Asia) and 22-25 at O'Hare Hilton for the CCSP report.

Only here 11th and 21st. Should have email contact in Madrid and Chicago, but Pune may be hit and miss. Still, not much need for too much contact at this time.

I'll give the diagrams and other issues some thought whilst away. Albert will be in Pune.

Have a good few weeks and I hope the Landsea issue has subsided.

Cheers

Phil

At 15:50 03/02/2005, you wrote:

Dear CA

The zero order draft of Chapter 3 of the WG1 IPCC AR4 report is now available. Your contribution has helped us put together this draft, and we thank you very much. However, it is NOT yet the first draft; we recognize that it is incomplete in some places (for instance where some CAs did not come through, or through oversight), and we have not even reviewed it fully ourselves, given the tight timetable. So we are seeking constructive comments and your assistance on developing the first draft. What is most helpful is for you to suggest new text and references, and explicit changes. Not "such and such" is bad or needs fixing. We can not promise to use the new text because there are 60 CAs who may well suggest different things. We also have to limit page numbers, so we especially welcome suggestions for shortening. If you care to rewrite a section more succinctly, then we will gladly consider it. The figures are all preliminary and will be thoroughly examined in Beijing in May, so suggestions of improved or more recent figures are welcomed. We also welcome copies of any papers submitted or referred to.

I am sending this out in two parts. This part has the text attached as a pdf. It is order 1 MB. The second part includes the figures, many in color, and it is 3.7 MB. We need you comments by 1 April 2005 at the latest. If you prefer to focus only on the section in which your contribution appeared, then that is fine, but you are welcome to comment on other parts as well. If you can not comment or prefer not to for some reason or another, a message to that effect would also be welcomed so we can track responses.

Please send your comments, preferably in word, with your name on each page, and clear identification of section, page and line number or figure number. You may like to make a comment, followed by explicit suggestion for addition or change. Please do justify and argue why the change is needed. Please send comments to Kevin Trenberth and Phil Jones, who will assemble them.

Many thanks for your help

Kevin Trenberth

Subject: Re: FW: "hockey stock" methodology misleading

Hi Andy,

The McIntyre and McKittrick paper is pure scientific fraud. I think you'll find this reinforced by just about any legitimate scientist in our field you discuss this with. Please see the RealClimate response:

[1]<http://www.realclimate.org/index.php?p=111>
and also:

[2]<http://www.realclimate.org/index.php?p=114>

The Moberg et al paper is at least real science. But there are some real problems with it (you'll want to followup w/ people like Phil Jones for a 2nd opinion).

While the paper actually reinforces the main conclusion of previous studies (it also finds the late 20th century to be the warmest period of the past two millennia), it challenges various reconstructions

using tree-ring information (which includes us, but several others such as Jones et al, Crowley, etc). I'm pretty sure, by the way, that a very similar version of the paper was rejected previously by Science. A number of us are therefore very surprised that Nature is publishing it, given a number of serious problems:

Their method for combining frequencies is problematic and untested:

A. they only use a handful of records, so there is a potentially large sampling bias.

B. worse, they use different records for high-frequencies and low-frequencies, so the bias isn't even the same--the reconstruction is apples and oranges.

C. The wavelet method is problematic. We have found in our own work that you cannot simply combine the content in different at like frequencies, because different proxies have different signal vs. noise characteristics at different frequencies--for some records, their century-scale variability is likely to be pure noise. They end up therefore weighting noise as much as signal. For some of the records used, there are real age model problems. The timescale isn't known to better than +/- a couple hundred years in several cases. So when they average these records together, the century-scale variability is likely to be nonsense.

D. They didn't do statistical verification. This is absolutely essential for such reconstructions (see e.g. the recent Cook et al and Luterbacher et al papers in Science). They should have validated their reconstruction against long-instrumental records, as we and many others have. Without having done so, there is no reason to believe the reconstruction has any reliability. This is a major problem w/ the paper. It is complicated by the fact that they don't produce a pattern, but just a hemispheric mean--that makes it difficult to do a long-term verification. But they don't attempt any sort of verification at all! There are some decades known to be warm from the available instrumental records (1730s, some in the 16th century) which the Moberg reconstruction completely misses--the reconstruction gives the impression that all years are cold between 1500 and 1750. The reconstruction would almost certainly fail cross-validation against long instrumental records. If so, it is an unreliable estimate of past changes.

We're surprised the Nature Reviewers didn't catch this.

E. They also didn't validate their method against a model (where I believe it would likely fail). We have done so w/ our own "hybrid frequency-domain" method that combines information separately at low and high-frequencies, but taking into account the problem mentioned above. This is described in:

Rutherford, S., Mann, M.E., Osborn, T.J., Bradley, R.S., Briffa, K.R., Hughes, M.K., Jones, P.D., [3]Proxy-based Northern Hemisphere Surface Temperature Reconstructions: Sensitivity to Methodology, Predictor Network, Target Season and Target Domain, Journal of Climate, in press (2005).

In work that is provisionally accepted in "Journal of Climate" (draft attached), we show that our method gives the correct history using noisy "pseudoproxy" records derived from a climate model simulation with large past changes in radiative forcing. Moberg et al have not tested their method in such a manner.

F. They argue selectively for favorable comparison w/ other work:

(1) Esper et al: when authors rescaled the reconstruction using the full instrumental

record (Cook et al, 2004), they found it to be far more similar to Mann et al, Crowley and Lowery, Jones et al, and the roughly dozen or so other empirical and model estimates consistent w/ it. Several studies, moreover [see e.g.: Shindell, D.T., Schmidt, G.A., Mann, M.E., Faluvegi, G., [4]Dynamic winter climate response to large tropical volcanic eruptions since 1600, Journal of Geophysical Research, 109, D05104, doi: 10.1029/2003JD004151, 2004.] show that extratropical, land-only summer temperatures, which Esper et al emphasises, are likely to be biased towards greater variability--so it's an apples and oranges comparison anyway.

(2) von Storch et al: There are some well known problems here: (a) their forcing is way too large (Foukal et al in Science a couple months back indicates maybe 5 times too large), DKMI uses same model, more conventional forcings, and get half the amplitude and another paper submitted recently by the Belgium modeling group suggests that some severe spin-up/initialization problems give the large century-scale swings in the model--these are not reproducible.

(3) Boreholes: They argue that Boreholes are "physical measurements" but many papers in the published literature have detailed the various biases in using continental ground surface temperature to estimate past surface air temperature changes--changing snow cover gives rise to a potentially huge bias (see e.g. : Mann, M.E., Schmidt, G.A., [5]Ground vs. Surface Air Temperature Trends: Implications for Borehole Surface Temperature Reconstructions, Geophysical Research Letters, 30 (12), 1607, doi: 10.1029/2003GL017170, 2003).

Methods that try to correct for this give smaller amplitude changes from borehole temperatures:

Mann, M.E., Rutherford, S., Bradley, R.S., Hughes, M.K., Keimig, F.T., [6]Optimal Surface Temperature Reconstructions using Terrestrial Borehole Data, Journal of Geophysical Research, 108 (D7), 4203, doi: 10.1029/2002JD002532, 2003]

[[7]Correction(Rutherford and Mann, 2004)]

Most reconstructions and model estimates still "sandwich" the Mann et al reconstruction. See e.g. figure 5 in: Jones, P.D., Mann, M.E., [8]Climate Over Past Millennia, Reviews of Geophysics, 42, RG2002, doi: 10.1029/2003RG000143, 2004.

Ironically, MM say our 15th century is too cold, while Moberg et al say it's too warm. Hmmm....

To recap, I hope you don't mention MM at all. It really doesn't deserve any additional publicity. Moberg et al is more deserving of discussion, but, as outlined above, there are some real problems w/ it. I have reason to believe that Nature's own commentary by Schiermeier will actually be somewhat critical of it.

I'm travelling and largely unavailable until Monday. If you need to talk, you can possibly reach me at 434-227-6969 over the weekend.

I hope this is of some help. Literally got to run now...

mike

At 02:14 PM 2/4/2005, Andy Revkin wrote:

Hi all,

There is a fascinating paper coming in Nature next week (Moberg of Stockholm Univ., et al) that uses mix of sediment and tree ring data to get a new view of last 2,000 years. Very warped hockystick shaft (centuries-scale variability very large) but still pronounced 'unusual' 1990's blade.

i'd like your reaction/thoughts for story i'll write for next thursday's Times.

also, is there anything about the GRL paper forthcoming from Mc & Mc that warrants a response?

I can send you the Nature paper as pdf if you agree not to redistribute it (you know the embargo rules).

that ok?

thanks for getting in touch!

At 12:03 PM 2/11/2005, Phil Jones wrote:

Mike,

Keith and Tim are here next week, but very busy with a proposal to the EU.

So you may have to hassle them a bit, or hang on for a week or two.

Nature dragged in the IPCC angle which annoyed me. I tried to explain to him how IPCC works. IPCC won't be discussing this in Beijing in May - except as part of Chapter 6. Hans von Storch will likely regret some of the words he's said.

FYI, just as NCAR have put up a web site to give the whole story re Chris Landseas's 'resignation' from a CA in the atmos. obs. chapter (to help Kevin Trenberth out), KNMI are doing the same re Rob van Dorland and that Dutch magazine. The chief scientist at KNMI has got involved as Rob didn't say the things attributed to him. I'll find out more on this in Pune as a guy from KNMI will be there.

Several other CAs on our chapter pulled out, or just didn't do anything. Their stories never got run.

Dick's report was good and my bit in Nature came across well.

Say hi to all there and wish Steve well.

Cheers

Phil

At 16:19 11/02/2005, Michael E. Mann wrote:

Phil--thanks, that's great. Really happy to hear that everyone is on board with this. I'm at a symposium honoring Steve Schneider out at Stanford right now. Lots of folks here--as I talk this over w/ them, and see Dick Kerr's coverage of this, etc. I realize it's not so bad--I was afraid this would be spun as bolstering the contrarians, but it hasn't. In large part due to quotes from you and others pointing out that the study actually reinforces the key conclusions, etc., and the fact Dick Kerr showed Keith and Tim's plot showing the scattering of multiple reconstructions, etc. which takes the focus off "Mann" a bit...

Nonetheless, I *am* convinced their methodology is suspect, as the analysis I sent shows. So I will really appreciate input from Keith, Tim, and you to make sure the language and wording are appropriate and fair...

I will revise as I get input from various people, with an aim to having this submission-ready in about 10 days (so you can have one final look after you return, and before you have to head out again).

looking forward to getting people's comments, feedback, etc.

thanks again,

mike

At 08:05 AM 2/11/2005, Phil Jones wrote:

Mike et al,

I've talked to Keith and Tim here and it seems best if we all come in with you on this response. What you have done is basically fine. We can discuss specific wording later.

My problem is that I'm off tomorrow to Pune till Feb 20 and email may be sporadic or non-existent. So can you discuss revised drafts with Keith and Tim, but keep me on - lower down as I'm away. I'm here on Feb 21 then off to Chicago to review the vertical temperature report for the NRC/NAS Feb 22-25.

Keep me on the emails in case email works well in Pune.

Cheers

Phil

At 23:35 10/02/2005, Michael E. Mann wrote:

Dear Caspar, Gene, Scott, Phil,

I am attaching a response I've drafted to the Moberg et al paper (attached for those of you who haven't seen it). The message is pretty clear and simple--their method overemphasizes the low-frequency variability. To demonstrate this, I've made use of stuff from Mann and Jones, and from the Mann/Rutherford/Wahl/Ammann J. Climate letter on Pseudoproxies. So I would welcome any of you to be co-authors on this--just let me now if you're interested. I've been in touch w/ Keith (he and Tim are potentially working on their own independent response--waiting to hear further).

This is a very rough draft, so comments much appreciated.

Looking forward to hearing back,

Mike

A good comparison of all of the reconstruction constructive by William Connelly, which makes it clear that the take-home point is robust, is available here:

mike

At 10:58 AM 2/14/2005, Tom Wigley wrote:

Mike,

I'm sorry we had no time to talk at Stanford.

Here is the answer to the LIA bounce back idea ...

For 20th century warming to be a bounce back, the heat must come from somewhere. The only source consistent with the bounce back idea is the ocean.

The Levitus data show that heat has been going INTO the ocean, not coming out of it.

This is really obvious, but I have never seem it stated anywhere.

Re WSJ. They say ...

"Statistician Francis Zwiers of Environment Canada, a government agency, says he now agrees that Dr. Mann's statistical method "preferentially produces hockey sticks when there are none in the data."

Dr. Mann, while agreeing that his mathematical method tends to find hockey-stick shapes, says this doesn't mean its results in this case are wrong. Indeed, Dr. Mann says he can create the same shape from the climate data using completely different math techniques."

It is a bit worrying that Francis agrees with M&M -- but it seems that you do too.

My questions are:

(1) Do other reconstructions (not including Lonnie Thompson's of course) suffer from this standardization problem?

(2) You have stated that simply averaging the data together gives the same result. Has this elementary method been published?

(2a) I note that the PC1 amplitude time series invariably correlates highly with the (non-areally-weighted) 'area average'. So this brings up the issue of whether you use some area weighting in your PCA -- as we

invariably do when doing PCA of gridded data?

(3) From what I can see without reading their full GRL paper, M&M think that the RE statistic has an odd sampling distribution. It is easy to show this by Monte Carlo simulation -- have you done this (i.e., in the abstract, as a statistical exercise, not for the specific case of MBH98, etc.)?

Tom.

Hi Mike,

On the personal stuff, I'd go with your first impressions, rather
than the perceptions of
others. This isn't a one-sided story. Anyway, I certainly want to
find out who is right
here and so I am open to writing more as the papers come out and the
facts become
clearer, just as I have written in the past about the Soon and
Balliunias business (p.
A3not bad) and about paleo-climate (p. 1 story in 2002 about Gary
Comers funding,
feature story on Lonnie Thompson's melting glaciers), etc. Would it
surprise you to
hear that anytime I write a story which seems to favor global
warming I am also deluged
by accusations of bias and demands for corrections etc.?
Regarding Moberg, I think the issue you are raising is a question of
emphasis and not a
matter for a correction. The specific sentences you're thinking of
(Indeed, new research

from Stockholm University on historical temperatures suggests past fluctuations were nearly twice as great as the hockey stick shows. That could mean the 20th-century jump isn't quite so anomalous.) seem to me be not only factual but precisely to the point of what the mainstream of science is discussing vis a vis MBH, which was the topic of that part of my story. For instance, in the Anderson/Woodhouse commentary that accompanied Moberg in the same issue of Nature, they too stress the increased variability just as I did and they make no mention of the late 1990s. And as per my email Monday, my article does also say that other reconstructions also indicate that the 20th Century was unusually warm and that the punch line is the same. Im sure youre fully sick of writing letters, but this may be right opportunity for a letter to the editor from you or someone who you can second. The person to send a letter to is [1]Karen.Pensiero@wsj.com. If you want, CC: me and my editor, [2]Elyse.tanouye@wsj.com. Or even an editorial on the broader topic of where the science is at. I can give you the name for who to send an editorial to if you want it. It is probably worth pointing out that no amount of debate can change the facts buried in those tree rings, etc.. Yes, I will continue to write about climate. The next topic is impacts. What do you think is the best story there? Id like to write about current impacts rather than only projected ones as these will be more tangible for the reader. Also, since the Arctic has been well covered Id be interested in impacts at lower latitudes. Antonio

B.8 Detailed implementation plan - first 18 months

MAX 40 PAGES

This section describes in detail the work planned to achieve the objectives of the proposed project up to its first 18 months in operation. The recommended length, excluding the forms specified below, is up to 15 pages. An introduction should explain the structure of this 18-month detailed implementation plan and how the plan will lead the participants to achieve the objectives aimed for by that time. It should also identify significant risks and contingency plans for these. The plan must be broken down into work packages (WPs) which should follow the logical phases of the project during this period, and include management of the project and assessment of progress and results to this point. Essential elements of the plan are:

- a) Detailed implementation plan introduction - explaining the structure of this plan and the overall methodology used to achieve the objectives of the first 18 months. Include a version of the form A3 which is used in Part A of the proposal, but covering just the first 18 months

b) Work planning, showing the timing of the different WPs and their tasks (Gantt chart or similar)

WP and Task leaders: Provide input (Max 4 pages per WP) with detail of plans including milestones and key deliverables

c) Graphical presentation of the components, showing their interdependencies (Pert diagram or similar)

d) Detailed work description broken down into work packages: Work package list (use work package list form below);

Deliverables list (use Deliverables list form below);

Description of each work package (use work package description form below, one per work package):

Note: The number and structure of work packages used must be appropriate to the complexity of the work and the overall value of the proposed project. Each work package should be a major subdivision of the proposed project and should also have a verifiable end-point (normally a deliverable or an important milestone in the overall project).

The planning should be sufficiently detailed to justify the proposed effort and allow progress monitoring by the Commission - the day-to-day management of the project by the consortium may require a more detailed plan.

Hi Phil,

At 02:29 21/02/2005, you wrote:

Francis,

Been away for the last week and off again tomorrow for the rest of this week. I was surprised to see comments from you in WSJ saying that McIntyre and McKittrick were likely right and the Mann reconstruction is wrong. I hope it is a case of misreporting !

Well, this isn't what I said, and its also not what is reported in the WJS article. The article quotes me as saying that the technique preferentially produces hockey sticks (actually, I **think** I said that it preferentially produces PC1s with hockey stick shapes, but that's a distinction that may have escaped the reporter - or I may have miss-spoken). In any case, this does not mean that the general form of the reconstruction (illustrating the unusual nature of the 20th century) is wrong - and I went to pains in the interview to also make that point.

The nearest composite reconstruction to MM in the 15th century is MBH98. All the others have the 15th century cooler than MBH98. There is no way MM are right in the 15th century. Also Moberg et al (2005) has too much long-term variability.

Sorry for the short email, I have loads of others to go through before

the end of today. We can discuss in more detail at Duke !

Unfortunately, I won't be at Duke because I'm still stuck in a particular type of Canadian purgatory called french training.

Cheers, Francis

Mike, Ray and Malcolm,

The skeptics seem to be building up a head of steam here ! Maybe we can use this to our advantage to get the series updated !

Odd idea to update the proxies with satellite estimates of the lower troposphere rather than surface data !. Odder still that they don't realise that Moberg et al used the Jones and Moberg updated series !

Francis Zwiers is still inside. He said that PC1s produce hockey sticks. He stressed that the late 20th century is the warmest of the millennium, but Regaldo didn't bother with that. Also ignored Francis' comment about all the other series looking similar to MBH.

The IPCC comes in for a lot of stick.

Leave it to you to delete as appropriate !

Cheers

Phil

PS I'm getting hassled by a couple of people to release the CRU station temperature data. Don't any of you three tell anybody that the UK has a Freedom of Information Act !

PRESSURE GROWING ON CONTROVERSIAL RESEARCHER TO DISCLOSE SECRET DATA

This should have produced a healthy scientific debate. Instead, Mr. Mann tried to shut down debate by refusing to disclose the mathematical algorithm by which he arrived at his conclusions. All the same, Mr. Mann was forced to publish a retraction of some of his initial data, and doubts about his statistical methods have since grown.

--The Wall Street Journal, 18 February 2005

But maybe we are in that much trouble. The WSJ highlights what Regaldo and McIntyre says is Mann's resistance or outright refusal to provide to inquiring minds his data, all details of his statistical analysis, and his code. So this is what I say to Dr. Mann and others expressing deep concern over peer review: give up your data, methods and code freely and with a smile on your face.

--Kevin Vranes, Science Policy, 18 February 2005

Mann's work doesn't meet that definition [of science], and those who use Mann's curve in their arguments are not making a scientific argument. One of Pournelle's Laws states "You can prove anything if you can make up your data." I will now add another Pournelle's Law: "You can prove anything if you can keep your algorithms secret."

--Jerry Pournelle, 18 February 2005

The time has come to question the IPCC's status as the near-monopoly source of information and advice for its member governments. It is probably futile to propose reform of the present IPCC process. Like most bureaucracies, it has too much momentum and its institutional interests are too strong for anyone realistically to suppose that it can assimilate more diverse points of view, even if more scientists and economists were keen to join up. The rectitude and credibility of the IPCC could be best improved not through reform, but through competition.

(1) HOCKEY STICK ON ICE

The Wall Street Journal, 18 February 2005

[1]http://online.wsj.com/article_email/0,,SB110869271828758608-IdjeoNmlah4n5yta4GHaqyIm4,00.html

On Wednesday National Hockey League Commissioner Gary Bettman canceled the season, and we guess that's a loss. But this week also brought news of something else that's been put on ice. We're talking about the "hockey stick."

Just so we're clear, this hockey stick isn't a sports implement; it's a scientific graph. Back in the late 1990s, American geoscientist Michael Mann published a chart that purported to show average surface temperatures in the Northern Hemisphere over the past

1,000 years. The chart showed relatively minor fluctuations in temperature over the first 900 years, then a sharp and continuous rise over the past century, giving it a hockey-stick shape.

Mr. Mann's chart was both a scientific and political sensation. It contradicted a body of scientific work suggesting a warm period early in the second millennium, followed by a "Little Ice Age" starting in the 14th century. It also provided some visually arresting scientific support for the contention that fossil-fuel emissions were the cause of higher temperatures. Little wonder, then, that Mr. Mann's hockey stick appears five times in the Intergovernmental Panel on Climate Change's landmark 2001 report on global warming, which paved the way to this week's global ratification -- sans the U.S., Australia and China -- of the Kyoto Protocol.

Yet there were doubts about Mr. Mann's methods and analysis from the start. In 1998, Willie Soon and Sallie Baliunas of the Harvard-Smithsonian Center for Astrophysics published a paper in the journal *Climate Research*, arguing that there really had been a Medieval warm period. The result: Messrs. Soon and Baliunas were treated as heretics and six editors at *Climate Research* were made to resign.

Still, questions persisted. In 2003, Stephen McIntyre, a Toronto minerals consultant and amateur mathematician, and Ross McKittrick, an economist at Canada's University of Guelph, jointly published a critique of the hockey stick analysis. Their conclusion: Mr. Mann's work was riddled with "collation errors, unjustifiable truncations of extrapolation of source data, obsolete data, geographical location errors, incorrect calculations of principal components, and other quality control defects." Once these were corrected, the Medieval warm period showed up again in the data.

This should have produced a healthy scientific debate. Instead, as the *Journal's* Antonio Regalado reported Monday, Mr. Mann tried to shut down debate by refusing to disclose the mathematical algorithm by which he arrived at his conclusions. All the same, Mr. Mann was forced to publish a retraction of some of his initial data, and doubts about his statistical methods have since grown. Statistician Francis Zwiers of Environment Canada (a government agency) notes that Mr. Mann's method "preferentially produces hockey sticks when there are none in the data." Other reputable scientists such as Berkeley's Richard Muller and Hans von Storch of Germany's GKSS Center essentially agree. We realize this may all seem like so much academic nonsense. Yet if there really was a Medieval warm period (we draw no conclusions), it would cast some doubt on the contention that our SUVs and air conditioners, rather than natural causes, are to blame for apparent global warming.

There is also the not-so-small matter of the politicization of science: If climate scientists feel their careers might be put at risk by questioning some orthodoxy, the inevitable result will be bad science. It says something that it took two non-climate scientists to bring Mr. Mann's errors to light.

But the important point is this: The world is being lobbied to place a huge economic bet -- as much as \$150 billion a year -- on the notion that man-made global warming is real. Businesses are gearing up, at considerable cost, to deal with a new regulatory environment; complex carbon-trading schemes are in the making. Shouldn't everyone look very carefully, and honestly, at the science before we jump off this particular cliff?

=====

(2) SCIENCE AND OPEN ALGORITHMS: "YOU CAN PROVE ANYTHING WITH SECRET DATA AND ALGORITHMS"

Jerry Pournell, 18 February 2005

[2]<http://www.jerrypournelle.com/view/view349.html#hockeystick>

Science and Open Algorithms: You can prove anything with secret data and algorithms.

There is a long piece on the global "hockey stick" in today's Wall Street Journal that explains something I didn't understand: Mann, who generated the "hockey stick" curve purporting to show that the last century was unique in all recorded history with its sharp climb in temperature, has released neither the algorithm that generated his curve nor the data on which it was based.

I had refrained from commenting on the "hockey stick" because I couldn't understand how it was derived. I've done statistical analysis and prediction from uncertainty much of my life. My first job in aerospace was as part of the Human Factors and Reliability Group at Boeing, where we were expected to deal with such matters as predicting component failures, and deriving maintenance schedules (replace it before it fails, but not so long before it fails that the costs including the cost of the maintenance crew and the costs of taking the airplane out of service are prohibitive) and other such matters. I used to live with Incomplete Gamma Functions and other complex integrals; and I could not for the life of me understand how Mann derived his famous curve. Now I know: he hasn't told anyone. He says that telling people how he generated it would be tantamount to giving in to his critics.

More on this after my walk, but the one thing we may conclude for sure is that this is not science. His curve has been distributed as part of the Canadian government's literature on why Canada supports Kyoto, and is said to have been influential in causing the "Kyoto Consensus" so it is certainly effective propaganda; but IT IS NOT SCIENCE. Science deals with repeatability and openness. When I took Philosophy of Science from Gustav Bergmann at the University of Iowa a very long time ago, our seminar came to a one-sentence "practical definition" of science: Science is what you can put in a letter to a colleague and he'll get the same results you did. Now I don't claim that as original for it wasn't even me who came up with it in the seminar; but I do claim Bergmann liked that formulation, and it certainly appealed to me, and I haven't seen a better one-sentence practical definition of science. Mann's work doesn't meet that definition, and those who use Mann's curve in their arguments are not making a scientific argument.

One of Pournelle's Laws states "You can prove anything if you can make up your data." I will now add another Pournelle's Law: "You can prove anything if you can keep your algorithms secret."

=====

(3) OPEN SEASON ON HOCKEY AND PEER REVIEW

Science Policy, 18 February 2005

[3]http://sciencepolicy.colorado.edu/prometheus/archives/climate_change/000355open_season_on_hocke.html

By Kevin Vranes

The recent 2/14 WSJ article ("Global Warring..." by Antonio Regaldo) addresses the debate that most readers of this site are well familiar with: the Mann et al. hockey stick. The WSJ is still asking - and trying to answer - the basic questions: hockey stick or no hockey stick? But the background premise of the article, stated explicitly and implicitly throughout, is that it was the hockey stick that led to Kyoto and other climate policy. Is it?

I think it's fair to say that to all of us in the field of climatology, the notion that Kyoto is based on the Mann curve is utter nonsense. If a climatologist, or a policy advisor charged with knowing the science well enough to make astute recommendations to his/her boss, relied solely on the Mann curve to prove definitively the existence of anthropogenic warming, then we're in deeper trouble than anybody realizes. (This is essentially what Stephan Ramstorf writes in a 1/27 RealClimate post.) And although it's easy to believe that national and international policy can hinge on single graphs, I

hope we give policy makers more credit than that.

But maybe we are in that much trouble. The WSJ highlights what Regaldo and McIntyre says is Mann's resistance or outright refusal to provide to inquiring minds his data, all details of his statistical analysis, and his code. The WSJ's anecdotal treatment of the subject goes toward confirming what I've been hearing for years in climatology circles about not just Mann, but others collecting original climate data.

As concerns Mann himself, this is especially curious in light of the recent RealClimate posts ([link](#) and [link](#)) in which Mann and Gavin Schmidt warn us about peer review and the limits therein. Their point is essentially that peer review is limited and can be much less than thorough. One assumes that they are talking about their own work as well as McIntyre's, although they never state this. Mann and Schmidt go to great lengths in their post to single out Geophysical Research Letters. Their post then seems a bit ironic, as GRL is the journal in which the original Mann curve was published (1999, vol 26., issue 6, p. 759), an article which is now receiving much attention as being flawed and under-reviewed. (For that matter, why does Table 1 in Mann et al. (1999) list many chronologies in the Southern Hemisphere while the rest of the paper promotes a Northern Hemisphere reconstruction? Legit or not, it's a confusing aspect of the paper that should never have made it past peer review.)

Of their take on peer review, I couldn't agree more. In my experience, peer review is often cursory at best. So this is what I say to Dr. Mann and others expressing deep concern over peer review: give up your data, methods and code freely and with a smile on your face. That is real peer review. A 12 year-old hacker prodigy in her grandparents' basement should have as much opportunity to check your work as a "semi-retired Toronto minerals consultant." Those without three letters after their name can be every bit as intellectually qualified, and will likely have the time for careful review that typical academic reviewers find lacking.

Specious analysis of your work will be borne out by your colleagues, and will enter the debate with every other original work. Your job is not to prevent your critics from checking your work and potentially distorting it; your job is to continue to publish insightful, detailed analyses of the data and let the community decide. You can be part of the debate without seeming to hinder access to it.

(4) CLIMATE CHANGE SCIENCE: TIME FOR TEAM "B"?

The American Enterprise Institute, 15 February 2005

[4]http://www.aei.org/publications/pubID.21974/pub_detail.asp

By Steven F. Hayward

The Intergovernmental Panel on Climate Change (IPCC) is currently working on its fourth assessment report. Despite the IPCC's noble intent to generate a scientific consensus, a number of factors have compromised the research and drafting process, assuring that its next assessment report will be just as controversial as previous reports in 1995 and 2001. Efforts to reform this large bureaucratic effort are unlikely to succeed. Perhaps the time has come to consider competition as the means of checking the IPCC's monopoly and generating more reliable climate science.

As the Intergovernmental Panel on Climate Change (IPCC) moves toward the release of its fourth assessment report (fourth AR) in 2007, the case of Chris Landsea offers in microcosm an example of why the IPCC's findings are going to have credibility problems. Last month Landsea, a climate change scientist with the U.S. National Oceanic and Atmospheric Administration (NOAA), resigned as a participant in the producing the report. Landsea had been a chapter author and reviewer for the IPCC's second assessment report in 1995 and the third in 2001, and he is a leading expert on hurricanes and related extreme weather phenomena. He had signed on with the IPCC to update the state of

current knowledge on Atlantic hurricanes for the fourth report. In an open letter, Landsea wrote that he could no longer in good conscience participate in a process that is "being motivated by pre-conceived agendas" and is "scientifically unsound." [1] Landsea's resignation was prompted by an all too familiar occurrence: The lead author of the fourth AR's chapter on climate observations, Kevin Trenberth, participated in a press conference that warned of increasing hurricane activity as a result of global warming. [2] It is common to hear that man-made global warming represents the "consensus" of science, yet the use of hurricanes and cyclones as a marker of global warming represents a clear-cut case of the consensus being roundly ignored. Both the second and third IPCC assessments concluded that there was no global warming signal found in the hurricane record. Moreover, most climate models predict future warming will have only a small effect--if any--on hurricane strength. "It is beyond me," Landsea wrote, "why my colleagues would utilize the media to push an unsupported agenda that recent hurricane activity has been due to global warming." [3] Landsea's critique goes beyond a fit of pique at the abuse of his area of expertise. The IPCC, he believes, has become thoroughly politicized, and is unresponsive to criticism. "When I have raised my concerns to the IPCC leadership," Landsea wrote, "their response was simply to dismiss my concerns." [4]

Landsea's frustration is not an isolated experience. MIT physicist Richard Lindzen, another past IPCC author who is not participating in the fourth report, has written: "My experiences over the past 16 years have led me to the discouraging conclusion that we are dealing with the almost insoluble interaction of an iron triangle with an iron rice bowl." (Lindzen's "iron triangle" consists of activists misusing science to get the attention of the news media and politicians; the "iron rice bowl" is the parallel phenomenon where scientists exploit the activists' alarm to increase research funding and attention for the issue. [5]) And Dr. John Zillman, one of Australia's leading climate scientists, is another ex-IPCC participant who believes the IPCC has become "cast more in the model of supporting than informing policy development." [6] And when the IPCC is not ignoring its responsible critics like Landsea and Lindzen, it is demonizing them. Not long ago the IPCC's chairman, Dr. Rajendra Pachauri, compared eco-skeptic Bjorn Lomborg to Hitler. "What is the difference between Lomborg's view of humanity and Hitler's?" Pachauri asked in a Danish newspaper. "If you were to accept Lomborg's way of thinking, then maybe what Hitler did was the right thing." [7] Lomborg's sin was merely to follow the consensus practice of economists in applying a discount to present costs for future benefits, and comparing the range of outcomes with other world problems alongside climate change. It is hard to judge what is worse: Pachauri's appalling judgment in resorting to *reductio ad Hitlerum*, or his abysmal ignorance of basic economics. In either case, it is hard to have much confidence in the policy advice the IPCC might have. [...]

Time for "Team B"?

The time has come to question the IPCC's status as the near-monopoly source of information and advice for its member governments. It is probably futile to propose reform of the present IPCC process. Like most bureaucracies, it has too much momentum and its institutional interests are too strong for anyone realistically to suppose that it can assimilate more diverse points of view, even if more scientists and economists were keen to join up. The rectitude and credibility of the IPCC could be best improved not through reform, but through competition....

(5) BRING THE PROXIES UP TO DATE!

Climate Audit, 20 February 2005

[6]<http://www.climateaudit.org/index.php?p=89#more-89>

Steve McIntyre

I will make here a very simple suggestion: if IPCC or others want to use "multiproxy" reconstructions of world temperature for policy purposes, stop using data ending in 1980 and bring the proxies up-to-date. Let's see how they perform in the warm 1990s - which should be an ideal period to show the merit of the proxies. I do not believe that any responsible policy-maker can base policy, even in part, on the continued use of obsolete data ending in 1980, when the costs of bringing the data up-to-date is inconsequential compared to Kyoto costs.

I would appreciate comments on this note as I think that I will pursue the matter with policymakers.

For example, in Mann's famous hockey stick graph, as presented to policymakers and to the public, the graph used Mann's reconstruction from proxies up to 1980 and instrumental temperatures (here, as in other similar studies, using Jones' more lurid CRU surface history rather than the more moderate increases shown by satellite measurements). Usually (but not always), a different color is used for the instrumental portion, but, from a promotional point of view, the juxtaposition of the two series achieves the desired promotional effect. (In mining promotions, where there is considerable community experience with promotional graphics and statistics, securities commission prohibit the adding together of proven ore reserves and inferred ore reserves - a policy which deserves a little reflection in the context of IPCC studies).

Last week, a brand new multiproxy study by European scientists [Moberg et al., 2005] was published in Nature. On the very day of publication, I received an email from a prominent scientist telling me that Mann's hockeystick was yesterday's news, that the "community" had now "moved on" and so should I. That the "community" had had no opportunity to verify Moberg's results, however meritorious they may finally appear, seemed to matter not at all.

If you look at the proxy portion of the new Moberg graphic, you see nothing that would be problematic for opponents of the hockey stick: it shows a striking Medieval Warm Period (MWP), a cold Little Ice Age and 20th century warming not quite reaching MWP levels by 1979, when the proxy portion of the study ends. (I'm in the process of examining the individual proxies and the Moberg reconstruction is not without its own imperfections.) In the presentation to the public - see the figure in the Nature article itself, once again, there is the infamous splice between reconstruction by proxy (up to 1980) and the instrumental record thereafter (once again Jones' CRU record, rather than the satellite record).

One of the first question that occurs to any civilian becoming familiar with these studies (and it was one of my first questions) is: what happens to the proxies after 1980? Given the presumed warmth of the 1990s, and especially 1998 (the "warmest year in the millennium"), you'd think that the proxy values would be off the chart. In effect, the last 25 years have provided an ideal opportunity to validate the usefulness of proxies and, especially the opportunity to test the confidence intervals of these studies, put forward with such assurance by the multiproxy proponents. What happens to the proxies used in MBH99 or Moberg et al [2005] or Crowley and Lowery [2000] in the 1990s and, especially, 1998?

This question about proxies after 1980 was posed by a civilian to Mann in December at realclimate. Mann replied:

Most reconstructions only extend through about 1980 because the vast majority of tree-ring, coral, and ice core records currently available in the public domain do not extend into the most recent decades. While paleoclimatologists are attempting to update many important proxy records to the present, this is a costly, and labor-intensive

activity, often requiring expensive field campaigns that involve traveling with heavy equipment to difficult-to-reach locations (such as high-elevation or remote polar sites). For historical reasons, many of the important records were obtained in the 1970s and 1980s and have yet to be updated. [my bold]

Pause and think about this response. Think about the costs of Kyoto and then think again about this answer. Think about the billions spent on climate research and then try to explain to me why we need to rely on "important records" obtained in the 1970s. Far more money has been spent on climate research in the last decade than in the 1970s. Why are we still relying on obsolete proxy data?

As someone with actual experience in the mineral exploration business, which also involves "expensive field campaigns that involve traveling with heavy equipment to difficult-to-reach locations", I can assure readers that Mann's response cannot be justified and is an embarrassment to the paleoclimate community. The more that I think about it, the more outrageous is both the comment itself and the fact that no one seems to have picked up on it.

It is even more outrageous when you look in detail at what is actually involved in collecting the proxy data used in the medieval period in the key multiproxy studies. The number of proxies used in MBH99 is from fewer than 40 sites (28 tree ring sites being U.S. tree ring sites represented in 3 principal component series).

As to the time needed to update some of these tree ring sites, here is an excerpt from Lamarche et al. [1984] on the collection of key tree ring cores from Sheep Mountain and Campito Mountain, which are the most important indicators in the MBH reconstruction: "D.A.G. [Graybill] and M.R.R. [Rose] collected tree ring samples at 3325 m on Mount Jefferson, Toquima Range, Nevada and 11 August 1981. D.A.G. and M.R.R. collected samples from 13 trees at Campito Mountain (3400 m) and from 15 trees at Sheep Mountain (3500 m) on 31 October 1983."

Now to get to Campito Mountain and Sheep Mountain, they had to get to Bishop, California, which is hardly "remote" even by Paris Hilton standards, and then proceed by road to within a few hundred meters of the site, perhaps proceeding for some portion of the journey on unpaved roads.

The picture below illustrates the taking of a tree ring core. While the equipment may seem "heavy" to someone used only to desk work using computers, people in the mineral exploration business would not regard this drill as being especially "heavy" and I believe that people capable of operating such heavy equipment can be found, even in out-of-the way places like Bishop, California. I apologize for the tone here, but it is impossible for me not to be facetious.

There is only one relatively remote site in the entire MBH99 roster - the Quelccaya glacier in Peru. Here, fortunately, the work is already done (although, needless to say, it is not published.) This information was updated in 2003 by Lonnie Thompson and should be adequate to update these series. With sufficient pressure from the U.S. National Science Foundation, the data should be available expeditiously. (Given that Thompson has not archived data from Dundee drilled in 1987, the need for pressure should not be under-estimated.)

I realize that the rings need to be measured and that the field work is only a portion of the effort involved. But updating 28 tree ring sites in the United States is not a monumental enterprise nor would updating any of the other sites.

I've looked through lists of the proxies used in Jones et al. [1998], MBH99, Crowley and Lowery [2000], Mann and Jones [2003], Moberg et al [2005] and see no obstacles to bringing all these proxies up to date. The only sites that might take a little extra time would be updating the Himalayan ice cores. Even here, it's possible that taking very short cores or even pits would prove adequate for an update and this might prove

easier than one might be think. Be that as it may, any delays in updating the most complicated location should not deter updating all the other locations.

As far as I'm concerned, this should be the first order of business for multiproxy studies.

Whose responsibility is this? While the costs are trivial in the scheme of Kyoto, they would still be a significant line item in the budget of a university department. I think that the responsibility here lies with the U.S. National Science Foundation and its equivalents in Canada and Europe. The responsibilities for collecting the proxy updates could be divided up in a couple of emails and budgets established.

One other important aspect: right now the funding agencies fund academics to do the work and are completely ineffective in ensuring prompt reporting. At best, academic practice will tie up reporting of results until the publication of articles in an academic journals, creating a delay right at the start. Even then, in cases like Thompson or Jacoby, to whom I've referred elsewhere, the data may never be archived or only after decades in the hands of the originator.

So here I would propose something more like what happens in a mineral exploration program. When a company has drill results, it has to publish them through a press release. It can't wait for academic reports or for its geologists to spin the results. There's lots of time to spin afterwards. Good or bad - the results have to be made public. The company has a little discretion so that it can release drill holes in bunches and not every single drill hole, but the discretion can't build up too much during an important program. Here I would insist that the proxy results be archived as soon as they are produced - the academic reports and spin can come later. Since all these sites have already been published, people are used to the proxies and the updates will to a considerable extend speak for themselves.

What would I expect from such studies? Drill programs are usually a surprise and maybe there's one here. My hunch is that the classic proxies will not show anywhere near as "loud" a signal in the 1990s as is needed to make statements comparing the 1990s to the Medieval Warm Period with any confidence at all. I've not surveyed proxies in the 1990s (nor to my knowledge has anyone else), but I've started to look and many do not show the expected "loud" signal e.g. some of the proxies posted up on this site such as Alaskan tree rings, TTHH ring widths, and theories are starting to develop. But the discussions so far do not explicit point out the effect of signal failure on the multiproxy reconstruction project.

But this is only a hunch and the evidence could be otherwise. The point is this: there's no need to speculate any further. It's time to bring the classic proxies up to date.

(6) CARELESS SCIENCE COSTS LIVES

The Guardian, 18 February 2005

[7]<http://www.guardian.co.uk/comment/story/0,3604,1417224,00.html>

Dick Taverne

In science, as in much of life, it is believed that you get what you pay for. According to opinion polls, people do not trust scientists who work for industry because they only care about profits, or government scientists because they suspect them of trying to cover up the truth. Scientists who work for environmental NGOs are more highly regarded. Because they are trying to save the planet, people are ready to believe that what they say must be true. A House of Lords report, Science and Society, published in 2000, agreed that motives matter. It argued that science and scientists are not value-free, and therefore that scientists would command more trust "if they openly declare the values that underpin their work".

It all sounds very plausible, but mostly it is wrong. Scientists with the best of

motives can produce bad science, just as scientists whose motives may be considered suspect can produce good science. An obvious example of the first was Rachel Carson, who, if not the patron saint, was at least the founding mother of modern environmentalism. Her book *The Silent Spring* was an inspiring account of the damage caused to our natural environment by the reckless spraying of pesticides, especially DDT.

However, Carson also claimed that DDT caused cancer and liver damage, claims for which there is no evidence but which led to an effective worldwide ban on the use of DDT that is proving disastrous. Her motives were pure; the science was wrong. DDT is the most effective agent ever invented for preventing insect-borne disease, which, according to the US National Academy of Sciences and the WHO, prevented over 50 million human deaths from malaria in about two decades. Although there is no evidence that DDT harms human health, some NGOs still demand a worldwide ban for that reason. Careless science cost lives.

Contrast the benefits that have resulted from the profit motive, a motive that is held to be suspect by the public. Multinationals, chief villains in the demonology of contemporary anti-capitalists, have developed antibiotics, vaccines that have eradicated many diseases like smallpox and polio, genetically modified insulin for diabetics, and plants such as GM insect-resistant cotton that have reduced the need for pesticides and so increased the income and improved the health of millions of small cotton farmers. The fact is that self-interest can benefit the public as effectively as philanthropy.

Motives are not irrelevant, and unselfish motives are rightly admired more than selfish ones. There are numerous examples of misconduct by big companies, and we should examine their claims critically and provide effective regulation to control abuses of power and ensure the safety of their products. Equally, we should not uncritically accept the claims of those who act from idealistic motives. NGOs inspired by the noble cause of protecting our environment often become careless about evidence and exaggerate risks to attract attention (and funds). Although every leading scientific academy has concluded that GM crops are at least as safe as conventional foods, this does not stop Greenpeace reiterating claims about the dangers of "Frankenfoods". Stephen Schneider, a climatologist, publicly justified distortion of evidence: "Because we are not just scientists but human beings as well ... we need to ... capture the public imagination ... So we have to offer up scary scenarios, make simplified dramatic statements, and make little mention of any doubts we have."

But in the end motives are irrelevant to the validity of science. It does not matter if a scientist wants to help mankind, get a new grant, win a Nobel prize or increase the profits of her company. It does not matter whether a researcher works for Monsanto or for Greenpeace. Results are no more to be trusted if the researcher declares his values and confesses that he beats his wife, believes in God, or is an Arsenal supporter. What matters is that the work has been peer-reviewed, that the findings are reproducible and that they last. If they do, they are good science. If not, not. Science itself is value-free. There are objective truths in science. We can now regard it as a fact that the Earth goes round the sun and that Darwinism explains the evolution of species. A look at the history of science makes it evident how irrelevant the values of scientists are. Newton's passion for alchemy did not invalidate his discovery of the laws of gravitation. To quote Professor Fox of Rutgers University: "How was it relevant to Mendel's findings about peas that he was a white, European monk? They would have been just as valid if Mendel had been a Spanish-speaking, lesbian atheist."

(8) HOW TO HANDLE ASTEROID 2004 MN4

Jens Kieffer-Olsen <dstdba@post4.tele.dk>

Dear Benny Peiser,

In CCNet 18/2005 - 11 February 2005 you brought an interesting article on the possible breakup of NEA 2004 MN4 in the year 2029:

> But there's another reason for concern. According to Dan
> Durda, another SWRI astronomer, 2004 MN4 is likely to be
> a "rubble-pile" asteroid, consisting of material only
> loosely held together by gravity. Because the asteroid
> will pass us at just 2.5 times Earth's diameter, tidal
> forces could tear it apart. The result would be a trail
> of rocks drifting slowly apart with the passage of time.
> One or more of these might hit Earth in the more distant
> future, creating a spectacular fireball as it burns up
> in the atmosphere.

> --Bill Cooke, Astronomy Magazine, 10 February 2005

First of all, a 300m asteroid could break into 100 pieces each larger than the Tunguska impactor. Secondly, the years for which a TS rating of 1 already exist for the object are NOT in the distant future, but 6, 7, and 8 years later.

That reminds us that neither the Torino nor the Palermo scale takes into account the possibility of such a MIRV'ed approach. Furthermore, the Palermo scale is designed to take into account the lead time. Even if 2004 MN4 were not to break up, the lead time to virtual impact in 2029 would be down to one sixth of the time to-day. In other words, if the post-2029 orbit is not being resolved before then, we may as well up the PS rating accordingly. If my math is correct, we should add 0.78 to its Palermo Scale rating, ie. $\log_{10}(6)$, for a total of -0.65.

Yours sincerely

Jens Kieffer-Olsen, M.Sc.(Elec.Eng.)

Slagelse, Denmark

(9) AND FINALLY: EUROPE FURTHER FALLING BEHIND IN TECHNOLOGY AND RESEARCH

EU Observer, 10 February 2005

[8]<http://www.euobserver.com/?aid=18382&print=1>

By Lucia Kubosova

BRUSSELS / EUOBSERVER - Europeans are still failing to show world leadership in technology and research, a new report shows.

The paper, published on Thursday (10 February) has evaluated the EU research and development programmes and their impact on Europe's knowledge-base and potential for innovation.

While it argues that EU funds for the programmes make a "major contribution", it suggests that more resources, industry participation and simplified administration are needed for them to have a greater effect in future.

"We have somehow lost momentum", said Erkki Ormala, chair of the panel issuing the report.

"The EU is falling behind. And we are now under pressure not only compared to our traditional rivals like the US or Japan, but also China, India or Brazil. We are facing a much tougher competition in talent and knowledge than we are used to".

Research Commissioner Janez Potocnik considers the paper's results as a reason for doubling the funds in his portfolio within the next budgetary period of 2007-2013.

"We don't want to achieve our economic growth by lowering the social or environmental standards. So to compete globally, we need to focus on knowledge", Mr Potocnik said to journalists, adding that the EU programmes should "make a bridge between practical innovation and research".

The report has listed several possible solutions for tackling outlined setbacks.

It argues that the EU must attract and reward the best talent, mobilise resources for innovation and boost cooperation between governments, businesses and universities in research.

It supports the idea of setting up a European Research Council to promote excellence and encourages more industry involvement, mainly on the part of small and medium-sized enterprises (SMEs).

However, SME representatives complain that their ideas about EU research and innovation funding are not taken into consideration.

"It's not about how big the budget is for SMEs and their involvement in such projects.

It is rather about the allocation of the funds. Most of them are granted for huge long-term projects which cost millions of euro and they can hardly attract smaller companies", according to Ullrich Schroeder, from UEAPME, the main umbrella organisation.

He argues that while several reports have already pointed out that SMEs must be more involved if the "Lisbon agenda" goal of 3 percent of GDP to be invested in research and development in the EU by 2010 is to be achieved, in reality they are not as well supported as huge transnational companies.

"It is not that the EU member states invest much less in universities than the US, but the greatest difference is that European SMEs are only investing 8% of the US amount, and it is simply not enough".

Mr Schroeder also said that while "there is a lot of rhetoric from politicians, that the SMEs should get involved, innovate and compete, when they come up with good projects, they are not sufficiently supported".

"The European Commission is more concerned about big companies and hightech areas, while innovation is needed also in more down-to earth sectors", Mr Schroeder told the EUobserver.

At 12:03 PM 2/11/2005, Phil Jones wrote:

Mike,

Keith and Tim are here next week, but very busy with a proposal to the EU.

So you may have to hassle them a bit, or hang on for a week or two.

Nature dragged in the IPCC angle which annoyed me. I tried to explain to

him how IPCC works. IPCC won't be discussing this in Beijing in May - except

as part of Chapter 6. Hans von Storch will likely regret some of the words he's said.

FYI, just as NCAR have put up a web site to give the whole story re Chris Landseas's

'resignation' from a CA in the atmos. obs. chapter (to help Kevin Trenberth out), KNMI

are doing the same re Rob van Dorland and that Dutch magazine. The chief scientist

at KNMI has got involved as Rob didn't say the things attributed to him. I'll find

out more on this in Pune as a guy from KNMI will be there.

Several other CAs on our chapter pulled out, or just didn't do anything. Their

stories

never got run.

Dick's report was good and my bit in Nature came across well.

Say hi to all there and wish Steve well.

Cheers

Phil

At 16:19 11/02/2005, Michael E. Mann wrote:

Phil--thanks, that's great. Really happy to hear that everyone is on board with this.

I'm at a symposium honoring Steve Schneider out at Stanford right now. Lots of folks

here--as I talk this over w/ them, and see Dick Kerr's coverage of this, etc. I realize

its not so bad--I was afraid this would be spun as bolstering the contrarians, but it hasn't. In large part due to quotes from you and others pointing out that the study actually reinforces the key conclusions, etc., and the fact Dick Kerr showed Keith and Tim's plot showing the scattering of multiple reconstructions, etc. which takes the focus off "Mann" a bit...
Nonetheless, I *am* convinced their methodology is suspect, as the analysis I sent shows. So I will really appreciate input from Keith, Tim, and you to make sure the language and wording are appropriate and fair...
I will revise as I get input from various people, with an aim to having this submission-ready in about 10 days (so you can have one final look after you return, and before you have to head out again).
looking forward to getting people's comments, feedback, etc.
thanks again,
mike

At 08:05 AM 2/11/2005, Phil Jones wrote:

Mike et al,
I've talked to Keith and Tim here and it seems best if we all come in with you on this response. What you have done is basically fine. We can discuss specific wording later.
My problem is that I'm off tomorrow to Pune till Feb 20 and email may be sporadic or non-existent. So can you discuss revised drafts with Keith and Tim, but keep me on - lower down as I'm away. I'm here on Feb 21 then off to Chicago to review the vertical temperature report for the NRC/NAS Feb 22-25.
Keep me on the emails in case email works well in Pune.

Cheers

Phil

At 23:35 10/02/2005, Michael E. Mann wrote:

Dear Caspar, Gene, Scott, Phil,
I am attaching a response I've drafted to the Moberg et al paper (attached for those of you who haven't seen it). The message is pretty clear and simple--their method overemphasizes the low-frequency variability. To demonstrate this, I've made use of stuff from Mann and Jones, and from the Mann/Rutherford/Wahl/Ammann J. Climate letter on Pseudoproxies. So I would welcome any of you to be co-authors on this--just let me now

if you're interested. I've been in touch w/ Keith (he and Tim are potentially working on their own independent response--waiting to hear further). This is a very rough draft, so comments much appreciated. Looking forward to hearing back,
Mike

Dear All,

I've knocked Chris off this reply. There is a meeting of the CCDD program next week

in Asheville. I guess Chris wants something for this. I'm on the panel, so if you want to

add to

what Gabi and Tom have put together then let me know and I'll feed that in additionally to

what is already there.

From being at the review last week of the vertical temperature trends panel, the

issue of

reducing forcing uncertainties is important. A number of people think that agreement in

the

20th century is all doing to model tuning due to uncertain forcing with sulphates. How to

counter this is one area. One of my own pet areas is trying to reduce uncertainties in the

paleo record for the last millennium, but again this is one of convincing people that we

really

know what has happened. So much is being made of the paleo records, but are they that

important to detection when most of the work is going on with the 20th century records. Is

the

pre-20th century really that important when it comes to D&A?

Cheers

Phil

At 20:45 28/02/2005, Gabi Hegerl wrote:

Hi IDAG people,

Chris Miller needs some input on where detection is going and what should be funded,

appended is a list Tom and I sent him as rapid response, but it sounds like they are

still

in the process of thinking about

this, so please reply (soon) if you have additions/comments (Chris, only thought of

sending

this now, I hope results will be still helpful)

Gabi

1) extending detection to other fields, esp. U.S. possible variables are circulation, anything hydrological (drought, average rainfall), climate extremes, storms, all this is getting more feasible as observational data get better, reanalyses get more reliable (although trend sstill questionable), and models get better and have higher resolution

2) compiling "showable" scorecard of what has been detected in the system already

3) abrupt changes - Tom thinks the relevance has been overstated of past changes in the thermohaline circulation (because of proximity of massive amounts of ice/freshwater). However, I think it would still be useful to find a fingerprint of predictors for thermohaline shutdown (from waterhosing experiments), and establish how early warning signs can be detected. Another aprupt change that could be dealt with are events such as the mega drought cycles in the western U.S., which our preliminary work indicates does not correspond with multidecal peaks in warmth for zonal average temperatures.

4) using paleoclimate data for understanding regional responses to known forcings, such as pulse of volcanism in early 19th century. tests of a model's predictability on regional scales. this however would require ensemble runs and a fair amount of legwork, so probably would be best as a proposal than as an IDAG project.

5) more surface temperature detection as already donw, to keep analyzing 20th century from models as model diagnostic and evaluating how to get most model performance information out of this diagnostic. For this, updates of forcing estimates, particularly reduced sulfate aerosol uncertainties would be useful.

Gabi, I'm looking for some quick thoughts, which probably means just you and Tom.

Obviously, the rest of IDAG would have ideas but it would take some time to poll them (I could see it as an agenda item at the IDAG meeting). If you had a couple highlight items by Thursday morning, that would be helpful as I have an internal meeting where this will be discussed.
Thanks again, Chris
Gabi Hegerl wrote:

Chris, by when do you need this? From the whole IDAG or just, eg from me and Tom?
Gabi
Chris Miller wrote:

Tom, Gabi, As you are probably aware, one of the recurring challenges for federal program managers is to indicate to upper management what the science priorities in the future should be. NOAA is more future-looking than it has been in the past and we are now being called upon more frequently to respond to this question. A simplistic answer would be "more of the same" since we are doing such good work now. This could be part of the answer, but not the whole answer. NOAA is interested in new science thrusts, new observational programs or analyses, new institutional arrangements, etc. (the "new is better syndrome"). I would appreciate it if you could take a few minutes to think about this issue and send me a few bullets on where you think the community should be going on D&A, for both continuing and new investments (from the perspective of the work that IDAG has been involved in to date).
Thanks for your help and look forward to the next IDAG mtg.
Chris

Subject: Glacier box - comments and suggestions  
Date: Sun, 6 Mar 2005 18:14:37 +0300 (MSK)  
Reply-to: olgasolomina@yandex.ru

Dear Valerie, Keith, Eystein and Peck,

Here are my comments on the glaciers box and suggestions for some improvements. I apologize that I am commenting the text that I was supposed to write myself, but we all know the reason - it was done in a rush and I had very limited access to the literature in the fall. I spent two weeks in Lamont (just came back) and had opportunity to read more. I want to say that I very much appreciate the help and contribution from all people who saved the situation to get the draft for the ZOD, and I hope that we can sharpen it further now.

In general my main concerns are the following:

1. We are focusing on the continuous records, which is one of the main achievements of the last years, indeed. But the real continuous records come from Scandinavia only - even the Alps are mostly based on moraine datings (wood etc.). The records from FJL and Brooks Range are not continuous, they are just the same as in any other place in the World, presented as continuous curves. So, two potential strategies can be suggested - to forget the rest of the World and keep the picture Scandinavia and Alps only or add more discontinuous records drawn as curves. I would go for the second solution for obvious reason to keep the global perspective. I attach more curves that I got from publications + I asked Tom Lowell and Wibjorn Karlen to make something of this kind for NZealand and Africa. I suggest to focus in detail (with dates etc.) on the Scandinavian records (as we did in our text), but briefly discuss the general picture of Holocene glacier variations referring to the updated picture. I need your opinion before changing the graphics (see comments and suggestions in "Box comments SO" file)

2. During a good half of the Holocene the glaciers were SMALLER than now. I attach here the figure with the same axes as at the Valerie's picture (warmest/wettest periods), and the detailed comments on it. To be scientifically correct we probably can shade these periods for the regions that we are presenting at our figure (see a separate file "smaller than now"). What is unusual about the modern retreat is the RATE, though we do not know much about the rate of the former retreat (again because of the lack of continuous records).

3. I changed the introduction. I believe that it is really important to keep the general perspective and mention the exceptions, namely glacier advances (at a Holocene global scale) reflect mostly temperature, therefore a kind of global synchronicity can be visible, though occasionally precipitation may trigger certain advances - maritime and tropical regions are likely to experience it more often than the rest of the World). Two papers justifying this point of view appeared recently (Oerlemans, 2005, Mayewski et al., 2004) and deserve attention. I

included the refs in the updated text. I am ready to discuss further this part, but I believe that we need changes here!

I am aware that this will require rather big changes in the text and figure, but I hope we are still at the stage when we can change, can we?

I will come soon with comments on the whole text and suggestions for the links to Ch4 (cryosphere), but I am really concern about those glaciers in the box, you knowà

Regards,  
olga

Thanks! Peck

Mike,

On Horizon, I'm supposed to be called in a few minutes by someone. Not sure who yet. This program is generally good. They did something on global dimming a few months ago and now want to do something on the truth about global warming, IPCC and skeptics.

That's all I know so far. Person's name is Paul Olding. Should be calling at 2pm, so 5 minutes time.

Cheers

Phil

At 13:21 17/03/2005, Michael E. Mann wrote:

HI Phil,

I agree-like all of these sources (e.g. boreholes, tree-rings, etc.) each one has its own potential weaknesses--in this case, I think cold-season precip could be playing a greater role w/ the mid-latitude glaciers than Oerlemans cares to admit. Not clear that should give a systematic bias towards underestimating temperature variations though, which is the argument you'd need to make if you're a boreholer.

The important thing is that it is entirely independent of everything else that has come before, and looks remarkably like the Bradley and Jones/Mann et al/Jones et al/Crowley & Lowery/Mann & Jones type reconstructions. Somehow the word hasn't really gotten out on this.

I've got a call in from a different BBC reporter today, Ben Dempsey, who seems much better. He's doing something for "Horizon" on climate change.

Do you know anything about this?

Thanks,

mike

At 08:02 AM 3/17/2005, Phil Jones wrote:

Mike,

Reporter was Paul Rincon ("Paul Rincon-NEWSi" <Paul.Rincon@bbc.co.uk>). No-one seems to have picked up on Oerleman's paper yet. You did send me that earlier, so I should have told him about that.

Sarah Raper here has some doubts about Oerleman's work, but it does reproduce the curve very well. Need to be objective though in interpreting it.

Cheers

Phil

At 12:48 17/03/2005, Michael E. Mann wrote:

Hi Phil,

Yes, BBC has been disappointing in the way they've dealt with this--almost seems to be a contrarian element there.

Do you remember the name of the reporter you spoke to?

Thanks,

Mike

p.s. Interesting that they also don't seem to be aware of the Oerleman's paper, which reproduces the "Hockey Stick" using completely independent data and method (glacial mass balance). I've attached in case you haven't seen...

At 03:26 AM 3/17/2005, Phil Jones wrote:

Ray,

I tried to convince the reporter here there wasn't a story, but he went with it anyway.

At least he put in a quote from me that there are loads of other series that show similar-ish series to MBH and MJ. Had to mention the Moberg et al series to achieve this.

The reporter said he'd not seen Moberg et al., and it wasn't flagged up by Nature to them at the appropriate time. Odd ! Then why are you running with this GRL paper as there are 10s issued each week. Well, it turns out, not surprisingly, that MM have issued numerous press releases themselves - using their networks.

Waterhouse is at Anglian Polytechnic Uni (APU) - it's in Cambridge and Chelmsford. Keith said what does John Waterhouse know about paleo - my thoughts also ! We've worked with John several years ago on an isotopes in trees project, that didn't produce much. APU is OK when it comes to counselling studies. Ruth works for them teaching at Yarmouth !

His quote is typical of many I get to here. Pity the reporter didn't mention this to me.

My response would have been what is the point of doing any more paleo work, if we are constrained by the answer we are allowed to get. If we don't have the MWP and LIA then we are wrong. We have orders of magnitude more data than when these came into vogue in the 1960s, but we still are expected to find them.

Cheers

Phil

Ben,

I will be at Duke. Get to the airport about 6.30pm on the 29th. Looking forward to seeing you there.

I should have signed off on the CCSP report by Easter. We have to get everything done by March 28. We had a conf. call last Friday.

I can see the argument about an assessment and 'new information'. It is a similar thing in IPCC. Glad to hear you're going to submit it for a paper, because I think it is important. It will unlikely change some peoples views, though.

Just had a long call with Chris Folland. He says that the next CCSP vtt meeting is going to be scheduled for Chicago for the week we should be doing the HC review ! Hope you're still going to come to Exeter. You should have less to do than all the other chapters !

See you on the 29th late or more likely for breakfast on the 30th.

Cheers

Phil

At 23:16 18/03/2005, you wrote:

Dear Phil,

Sorry about the delay in replying to your email. I picked up a chest infection while I was at the IPCC meeting in Hawaii, and it proved to be very persistent. I think a weekend's rest will do me good.

It was great to see you in Chicago, even though the meeting itself was quite difficult to sit through. As may have been apparent, Roger and I really rub each other the wrong way. Working with him on this CCSP Report has been a very unpleasant experience. I am taking your advice, and trying to write up the "amplification factor" stuff that I showed in Chicago. I presented this in Hawaii, and it sparked a lot of discussion. Just between you and me, Susan Solomon argued quite forcefully that this new information should NOT go into the CCSP Report, and that we should not be performing science in support of an assessment. She was concerned that the CCSP Report might be subject to unjustified criticism if key conclusions of the Report relied on unpublished work. I have considerable sympathy with this view. It does seem important to get this work submitted to a peer-reviewed publication as soon as possible, and then worry later about whether the material should or should not appear in CCSP.

Are you going to the Duke IDAG meeting? If so, I look forward to seeing you there.

Best regards to you and Ruth,

Ben

Cc: Peter Thorne <peter.thorne@metoffice.gov.uk>

Philip,

I'm not unhappy at all. If I am it is more about HadCRUT2 and 3.

I read through the report to DEFRA and will be sending some comments later today. I also commented on what Harry has written as a report for you. I've left those comments with him as he's away this week and I'm off April 6-15.

It is a bit odd with HadCRUT2 that the problem has surfaced now and my old mask hasn't made any difference.

Cheers

Phil

At 15:33 01/04/2005, Brohan, Philip wrote:

Phil.

I've just had a chat with Peter Thorne about HadCRUT2 and 3, and I get the impression that you are concerned, so we thought I should clarify what is going on. In particular I want to assure you that we are not trying to change the system without your approval.

To make things quite clear, we have two HadCRUT systems here:

1) Peter is running HadCRUT2. This is our operational system which produces the new data every month that we send to you and everyone. This is a fixed system, it does exactly what you agreed with Peter a couple of years ago. We don't plan to change it at all.

We did, unfortunately, make a mistake while running the system; we think a land-mask file was changed. This is what Peter's recent messages have been about. We're still not quite sure how this happened, but whatever fix we apply will be to restore the system to the original, agreed state.

2) I am coordinating HadCRUT3. This currently encompasses Harry's work on the data, Simon's work on blending, John Kennedy's work on variance correction, and my work on errors and gridding. Some combination of this work will become the new dataset.

I have a clear picture of what I think should form the new dataset. However, we won't produce HadCRUT3 unless you (and all the other contributors) agree. If I can't persuade you of the value of a change, it won't happen. In particular, I see the land station data as entirely under your control, both now and in the future.

If I (or Peter) misread the vibes and you were not worrying about any of this, please don't start. There are not serious problems with either system.

Have fun,

Philip.

Hi Keith and Tim - sorry for the delay in responding. I think the issues you raise are worth discussing, but we can do that in Beijing, and hopefully with Susan. She is keen on the idea, and my gut says it's a good idea to include such "crowley" plots somewhere - at least in the appendix, for example. But, let's talk in person.

In the meantime, we really need your comments on the ZOD - including what you feel has to be done with your section, but also with the others. We have comments from most others, and are expecting the external review comments soon, so please send yours ASAP so they can be included in this important stage.

Thanks! Best, peck

<david.easterling@noaa.gov>

Kevin,

I plan to look through your 3.4.1 draft tomorrow or later this week. At the same time I also plan to have a go at section 3.2. David has sent me some new figures and there are two new papers to add in. I am having difficulty finding some quality time at the moment, but hope this will come later this week.

I did read all the CCSP report. The review group are having a conf call tomorrow on this, but they have chosen your afternoon, so I can't take part. There were 6

reviewers of the review and one other almost wrote as much as you. Most were positive on the review saying that the report authors have a lot to do, particularly for Chapters 1 and 6. How all this pans out is impossible to tell. The next meeting of the authors is being scheduled for the week after Beijing.

I agree some of their figures are useful, but I too doubt whether we will have

much useful for the FOD we have to write. We will likely be doing them in parallel - which is hardly ideal.

I wouldn't send our 3.4.1 to Tom at this time - at least wait till Brian, David and I

have been through yours. Also I wouldn't want Tom passing it on to the CCSP VTT

authors. I think they will have a lot of hard thinking when they get the NRC review, to

worry too much about what we're doing. We do need to have our chapter and their

report meshing at some time, but this might have to wait till the SOD (by which time their report might be finished).

Cheers

Phil

At 17:35 18/04/2005, Parker, David (Met Office) wrote:

Kevin

Thanks. You have saved me some work because on my journey back from Geneva I also studied the comments on 3.4.1 (on paper) and was considering making an electronic revised section. I came to the conclusion that 3.4.1 should say that there are 2 schools of thought

about Fu et al and other aspects of the temperatures-aloft issue:  
the jury is still out. That would be a assessment (as opposed to a  
review) of the current state of the science. Fu may not be correct as he  
seems to imply upper tropospheric warming rates well outside the error-  
bars implied by the radiosondes (though I am aware of their problems  
too). I have not yet read your attachment but will consider it in the next  
few days.  
I looked at the surface temperature comments too and feel it may be  
best to wait until in Beijing, as most comments are about what diagrams  
to choose. I could try to re-order the urban warming section as  
reviewers suggest, but we may still wish to contact Tsutsumi (who didn't reply  
to my email a couple of months ago) to write something.

Regards

David

Dear All,

In addition to Kevin's comments and from a quickish look through parts of Chapters 4, 6 and 9, here are a few suggestions.

First for best use of time, I would suggest that Cluster B gets broken into two parts. Basically separating off the overlap with the paleo and instrumental record including borehole temperatures and glacier length changes from the sea ice/SST, snow/temperature. OHC/SST, salinity/precip and SLR etc. The latter can be dealt with by Chs 5, 3 and 4. The former is really for 6, 3 and 4.

Issues for 3 and 6 are the interface of the instrumental and paleo records, particularly how the early 19th century is dealt with. This period of instrumental records is believed by many in the paleo community not to exist, but in Europe and a few other regions it exists back in good order to the late 18th century. The 19th century is, I believe, the key to resolving much of the discussion about the millennium. Much more should be made of this period when comparisons with long forced GCM runs are analyzed. Europe may be a small continent, but the 200-250 year 'perfect proxy' records (which have all seasons!) need to be studied more. As any conclusions relate to Ch 6, the main text should be there, with perhaps a box on the early instrumental period in Ch 3.

Somewhat related to the above, Ch 4 has a section on the recent Oerlemans (2005) work - attached for reference. Mike Mann sent me a figure (see jpg) comparing this with most other reconstructions of parts of the millennium. It seems that this piece of work should be with all the others in Ch 6 and not Ch 4. When producing plots like this getting the right base level is crucial - not just for Oerlemans' series, but also for the boreholes. Also, the degree of smoothing and the y-scale used can easily determine the takeaway message.

Chapter 9 has an interest in both these issues.

Finally, there is one other issue. Do we want to consider having a web site (distributed?) where the data for some selected time series can be downloaded from - not just the smoothed/plotted series, but on the original timescale as well. This possibly comes back also to a consistent way of smoothing time series.

Cheers

Phil

Kevin Trenberth schrieb:

Hi Martin

Yes I will do this.

Firstly on cluster A:

I/we have an issue which is: what about changes in radiative forcing from water vapor (or feedback if you prefer), it is of order  $1 \text{ W m}^{-2}$ .

So this relates to water vapor changes in chapter 3.

Cluster B: Consistency in observed climate change: atmosphere, ocean, cryosphere. This may also extend to paleo, chapter 6.

Issues:

\*Consistency of:\*

- \* sea ice with SST
- \* snow cover with snowfall and temperature
- \* glacier melting and permafrost changes vs temperatures
- \* borehole temperatures, glacier changes and paleo record
- \* overlap between paleo record and instrumental record
- \* salinity vs precipitation
- \* ocean heat content with SST and surface fluxes
- \* sea level rise as an integrator: ocean expansion, melting of land ice, increased water storage on land, and changes in TOA radiation (presumably led by Chapter 5.)

Issues consist of use of consistent temperature and precipitation records (don't use NCEP surface temperatures as in Ch 4 CQ).

Points of contention:

- 1) consistency
- 2) overlap and redundancy
- 3) where to place integrated assessment?
  - \* sea level: Chapter 5
  - \* snow, ice, temperature chapter 3 section 3.9
  - \* paleo record vs instrumental chapter 6
  - \* overall view including sea level chapter 3, in 3.9
  - \* T increase (land, SST, subsurface ocean), snow retreat, sea ice retreat, thinning, freezing season shorter, glacier melt, sea level rise.
  - \* Precip changes, drought, salinity, ocean currents, P-E, snowfall.

Please see the draft of 3.9.

So in terms of the agenda, the main points are:

- 1) Ensuring consistency among variables across chapters
- 2) Agreement on which chapter and what person will handle what, and in particular, that 3.9 will have a look ahead aspect to the chapters that follow.

The above points could all be briefly on the table with the focus on cross-chapter issues.

Desirable to circulate draft section 3.9 (1 page).

Kevin,

Right on ! Assumes precip doesn't change - i.e. it's constant. Difficult to do much more for some regions, but could do a lot better for the Alps. Ch 4 has swallowed this hook, line and sinker and it is really a Ch 6 issue. Ch 6 wasn't even aware of it. Can't decide who on Ch 4 knew about it as Oerlemans isn't there and the Swiss Glacier people didn't know about the paper 2 weeks ago when I saw them.

I like the curve as does Mike Mann, but its not for any scientific reason.

Any jury is still out on whether this is right, but I'm glad someone has tried the approach. It is a quantification of what people have assumed, but there likely isn't enough detail in the paper to show how it was done.

I've not seen this paper in a proper issue of Science yet. As such I've not been able to get the supporting material.

This paper is totally independent of all other paleo work. It is much better science than Mobeg et al. in Nature in February. Susan has been sending a few emails to Ch 6 about how to display the various millennium series - some of which she's not thought through.

Just be glad we haven't got paleo in our chapter !

Cheers

Phil

Subject: Re: WG1 LA2 meeting - Overlap cluster A

Date: Wed, 20 Apr 2005 19:46:31 -0600 (MDT)

Cc: "Phil Jones" <p.jones@uea.ac.uk>, "Peter Lemke" <plemke@awi-bremerhaven.de>, "Susan Solomon" <ssolomon@al.noaa.gov>, ipcc-wg1@al.noaa.gov, k.briffa@uea.ac.uk

Martin I think you are right: the paleo instrumental issue is likely to involve mainly Briffa from Chap 6 and Phil from our chapter, so they might well spin off at some point. Are there others Phil?

Martin,

You are right, it should just be the two of us and as Keith is just across the corridor we can have the meeting beforehand or on the way together. If you add this though to your list of possible meetings you might find that some others are interested. This meeting of 3 and 6 can occur at the same time as 3 and 4, so during Cluster B. There does need to be some discussion between 4 and 6 though to decide where Oerlemans work is best located within AR4.

There is also the issue of Ch 9 as Kevin mentioned. As with Ch 4 using an NCEP temperature series for the Arctic, there might be issues with some other chapters using observed datasets which Ch 3 might think inappropriate or saying things about them that differ from what we do. Hopefully all these sorts of issues which get flagged when the overviews of the whole of AR4 get discussed (and also at LA3 and LA4).

Cheers  
Phil

>Hi Keith,

got this paper from Jens Hesselbjerg. Interesting with respect to the von Storch story.

Eystein

>A few comments in English:

>We have used a different version of the MPI coupled modeling system from that described by von Storch et al. to simulate the last 500 years. The model we have used has a different ocean component (OPYC in stead of HOPE) and a higher resolution in the atmosphere (T42 in stead of T31 - by many considered to be a substantial improvement in terms of representing synoptic behavior). Moreover, we have used different reconstructions of the external forcing. All these differnces leads to somewhat differnt behaviours compared to von Storch, and yet the model does seem to depict many of the observed major climatic events. Details are given in the paper.

Hi Keith and Phil - Thanks. I read this to say that the issue of pre-1860 instrumental data is figured out ok? Plan outlined below sounds good if ok with you both.

Best, Peck

Subject: Fwd: CCNet: DEBUNKING THE "DANGEROUS CLIMATE CHANGE" SCARE

Date: Wed Apr 27 09:06:53 2005

Mike,

Presumably you've seen all this - the forwarded email from Tim. I got this email from McIntyre a few days ago. As far as I'm concerned he has the data - sent ages ago. I'll tell him this, but that's all - no code. If I can find it, it is likely to be hundreds of lines of

uncommented fortran ! I recall the program did a lot more than just average the series.

I know why he can't replicate the results early on - it is because there was a variance correction for fewer series.

See you in Bern.

Cheers

Phil

Dear Phil,

In keeping with the spirit of your suggestions to look at some of the other multiproxy publications, I've been looking at Jones et al [1998]. The methodology here is obviously more straightforward than MBH98. However, while I have been able to substantially emulate your calculations, I have been unable to do so exactly. The differences are larger in the early periods.

Since I have been unable to replicate the results exactly based on available materials, I would appreciate a copy of the actual data set used in Jones et al [1998] as well as the code used in these calculations.

There is an interesting article on replication by Anderson et al., some distinguished economists, here [1]<http://research.stlouisfed.org/wp/2005/2005-014.pdf> discussing the issue of replication in applied economics and referring favorably to our attempts in respect to MBH98.

Regards, Steve McIntyre

Keith and Phil,

you both feature in the latest issue of CCNet:

#### (4) GLOBAL WARMING AND DATA

Steve Verdon, Outside the Beltway, 25 April 2005

[2]<http://www.outsidethebeltway.com/archives/10200>

A new paper ([3]<http://research.stlouisfed.org/wp/2005/2005-014.pdf>) from the St. Luis Federal Reserve Bank has an interesting paper on how important it is to archive not only the data but the code for empirical papers. While the article looks mainly at economic research there is also a lesson to be drawn from this paper about the current state of research for global warming/climate change. One of the hallmarks of scientific research is that the results can be replicable. Without this, the results shouldn't be considered valid let alone used for making policy.

Ideally, investigators should be willing to share their data and programs so as to encourage other investigators to replicate and/or expand on their results.<sup>3</sup> Such behavior allows science to move forward in a Kuhn-style linear fashion, with each generation seeing further from the shoulders of the previous generation.<sup>4</sup> At a minimum, the results of an endeavor-if it is to be labeled "scientific"-should be replicable, i.e., another researcher using the same methods should be able to reach the same result. In the case of applied economics using econometric software, this means that another researcher using the same data and the same computer software should achieve the same results.

However, this is precisely the problem that Steven McIntyre and Ross McKittrick have run into since looking into the methodology used by Mann, Hughes and Bradley (1998) (MBH98), the paper that came up with the famous "hockey stick" for temperature reconstructions. For example, this post here shows that McIntyre was prevented from accessing Mann's FTP site. This is supposedly a public site where interested researchers can download not only the source code, but also the data. This kind of behavior by Mann et. al. is simply unscientific and also rather suspicious. Why lock out a researcher who is trying to verify your results...do you have something to hide professors Mann, Bradley and Huges? Not only has this been a problem has this been a problem for McIntyre with regards to MBH98, but other studies as well. This post at Climate Audit shows that this problem is actually quite serious.

Crowley and Lowery (2000)

After nearly a year and over 25 emails, Crowley said in mid-October that he has misplaced the original data and could only find transformed and smoothed versions. This makes proper data checking impossible, but I'm planning to do what I can with what he sent. Do I need to comment on my attitude to the original data being "misplaced"?

Briffa et al. (2001)

There is no listing of sites in the article or SI (despite JGR policies requiring citations be limited to publicly archived data). Briffa has refused to respond to any requests for data. None of these guys have the least interest in some one going through their data and seem to hoping that the demands wither away. I don't see how any policy reliance can be made on this paper with no available data.

Esper et al. (2002)

This paper is usually thought to show much more variation than the hockey stick. Esper has listed the sites used, but most of them are not archived. Esper has not responded to any requests for data. '

Jones and Mann (2003); Mann and Jones (2004)

Phil Jones sent me data for these studies in July 2004, but did not have the weights used in the calculations, which Mann had. Jones thought that the weights did not matter, but I have found differently. I've tried a few times to get the weights, but so far have been unsuccessful. My surmise is that the weighting in these papers is based on correlations to local temperature, as opposed to MBH98-MBH99 where the weightings are based on correlations to the temperature PC1 (but this is just speculation right now.) The papers do not describe the methods in sufficient detail to permit replication.

Jacoby and d'Arrigo (northern treeline)

I've got something quite interesting in progress here. If you look at the original 1989 paper, you will see that Jacoby "cherry-picked" the 10 "most temperature-sensitive" sites from 36 studied. I've done simulations to emulate cherry-picking from persistent red noise and consistently get hockey stick shaped series, with the Jacoby northern treeline reconstruction being indistinguishable from simulated hockey sticks. The other 26 sites have not been archived. I've written to Climatic Change to get them to intervene in getting the data. Jacoby has refused to provide the data. He says that his research is "mission-oriented" and, as an ex-marine, he is only interested in a "few good" series.

Jacoby has also carried out updated studies on the Gaspé series, so essential to MBH98. I've seen a chronology using the new data, which looks completely different from the old data (which is a hockey stick). I've asked for the new data, but Jacoby-d'Arrigo have refused it saying that the old data is "better" for showing temperature increases. Need I comment? I've repeatedly asked for the exact location of the Gaspé site for nearly 9 months now (I was going to privately fund a re-sampling program, but Jacoby, Cook and others have refused to disclose the location.) Need I comment?

Jones et al (1998)

Phil Jones stands alone among paleoclimate authors, as a diligent correspondent. I have data and methods from Jones et al 1998. I have a couple of concerns here, which I'm working on. I remain concerned about the basis of series selection - there is an obvious risk of "cherry-picking" data and I'm very unclear what steps, if any, were taken to avoid this. The results for the middle ages don't look robust to me. I have particular concerns with Briffa's Polar Urals series, which takes the 11th century results down (Briffa arguing that 1032 was the coldest year of the millennium). It looks to me like the 11th century data for this series does not meet quality control criteria and Briffa was over-reaching. Without this series, Jones et al. 1998 is high in the 11th century. Note that none of this actually "disproves" the global warming hypothesis. However, it does raise very, very serious questions in my opinion. We are talking about enacting policies to curb global warming that could cost not billions, but trillions of dollars. Shouldn't we at least be allowed to see the source code, the data and ask for replication at a minimum? I think the answer is simple: YES!!

Ben,

Tom was here yesterday. He said you were going to the CCSP meeting for a day in Chicago, then flying on to the UK for the HC meeting May 18-19 (and 17th evening). Do you still want to come on up to Norwich afterwards?

Glad to hear from Tom you've been writing up your CCSP chapter and extending it significantly. He gave me a brief summary. I signed off yesterday on the CCSP report. You should be getting it through Tom Karl later today, or by Monday. As I did Ch 5, if you want to check anything with me feel free to. I wasn't able to stop some comments being put in by Lindzen, but Tom has a paper as does Myles which are enough to ignore his and the Douglass papers.

Cheers

Phil

Apologies

Phil

Kevin,

Finally gotten around to putting thoughts down. Mostly on the challenges slides at the start. Maybe you would have said these things.

1. As well as suggesting the model chapters rank models (I don't think they will go with this - even though it is what we should be doing, and there are a whole raft of issues as to how to do it) should we also be dismissing observational papers that are clearly wrong (or a distortion of the facts and emphasizing the wrong issues).

In some parts of our chapter, we omit the poor papers. Just stressing that we are doing an assessment and not a review. An assessment is our expert view of the science at the present.

For space limitations we must omit many papers, but we must do this objectively. In the NRC review I made the point that most of the papers reviewed were the author's own. It is difficult and we must not fall into that trap. All this again comes back to assessment/review.

With 3.4.1 we mustn't get caught up in having to agree with the CCSP VTT report. We're either doing OUR assessment or we might as well give up.

Gone on for long enough on that one.

2. I think we both believe we should be saying somewhere what we should be measuring (how accurately, where and with what). If we don't say this somewhere, AR5 will be in a worse state. Susan is against this, but I think on this point she's wrong. IPCC has a lot of clout - much more than GCOS and/or WMO. It should be saying something about what we should be doing.

3. Minor point, just land warming more than ocean, not much more.

4. I guess you've expanded on linear trends enough

5. The CCSP diagrams are good, but I'm not keen on running means. I guess though they wouldn't be too different with a better smoother.

6. I guess you'll raise map projections. Could add in the new one Dave has done for precip to show the 30E edge.

The additional slides. Most of these are from a talk I have to give in Bern next month.

They relate

mostly to issues with Ch 6. Maybe you can add a couple of them. They relate to the issues of:

- making full use of the instrumental records to compare with proxy records

- changes in seasonality

- was the few hundred years before 1850 always colder than the post 1920 period.

Kevin et al,

The diagram looks too good to me. CRU's data are reasonable over Brazil for some of the period, but poor in others, particularly recently. So we would have difficulty in updating this because of station numbers and quality. We could try using the GPCC dataset. They have huge numbers of stations for Brazil, but only for specific regions and periods, so likely problems there also.

We have a couple of papers in submission to J. Hydrology on flows in the subcatchments of the Parana river, which are well reproduced by rainfall, evaporation and a catchment model. Agree with your concerns about the Amazon flows not agreeing with the rainfall. Do the NAR and SAR regions fully encompass the enormous catchment though.

Cheers

Phil

At 17:36 03/05/2005, Aiguo Dai wrote:

One can use the Chen et al. and CRU to produce similar type of plots to validate Marengo's result.

He did use the CRU rainfall data set, but not for this particular plot.

Aiguo

Kevin Trenberth wrote:

Hi all

As you know we got some manuscripts from Jose Marengo to be considered in our chapter, and he is a LA on another chapter and will be in Beijing. He has offered to be CA.

My question concerns how good his data are? I asked Aiguo Dai to comment:

=====

One of the interesting results from Marengo's work is that he found the Northern and Southern Amazonia have opposite phase of decadal rainfall variations (see attached Fig. from Marengo 2004, Ther. Appl. Climatol.): In the northern Amazonia, rainfall is above normal during ~1945-1975 and below normal during ~1976-1998; and it is opposite in the southern Amazonia. He suggested warmer SST in central and eastern Pacific contributed to the dry conditions in the northern Amazonia during 1976-1998.

As noted in Betts et al. (2005, JHM, in press), Marengo's basin integrated rainfall index does not correlate well with Amazon river flow during the recent decades (worse than Chen et al.). This large multidecadal signal seems, however, robust.

=====

Certainly the attached figure is striking. Are we sure it is not due to changes in the way observations are made? Do other datasets replicate this? The lack of relation with

river flow is a substantial concern. Matilde, can you provide informed commentary? If the figure is good then maybe we should include it?

Kevin

Dear all,

First of all a big hand for Eystein and all those who put in so much time into this task. Very disheartening to hear the outcome.

I have much sympathy with what Rainer Zahn has said, especially on the Brussels front and the client relationships that are cultivated with EU officials.

I think that in addition to a letter to the EU, I would suggest that perhaps an editorial in NATURE or something similar, outlining the growing degree of scepticism amongst scientists regarding the transparency of the EU funding process might be in order.

Subject: commission performance alpha 5

dear Eystein, dear Imprint consortium,

I am sure I will not make many friends with what follows below. Firstly, it surely is sad and disheartening to see our proposal going down. and there are many issues involved some of which have been named in the recent emails. But then there are those issues left that have not been named but which I consider relevant if we are to make progress on the EU FWP front. Some of these issues may and will touch a personal nerve here and there, but let's face some of the unpleasant realities much rather than sitting back and keeping going with business as usual, a business that soon may go out of existence.

First, I am not convinced that Imprint was the best we could have done. On my side I was surprised to no small extent during our London meeting to see that those from the modeling community and other groups present obviously had no idea why our palaeo-component (a derivative of the planned ICON IP) was part of Imprint, and they were not overly favourable to listen and expand their views. So in a sense, even within our own consortium there was, perhaps still is a lack of insight and understanding as to what a palaeo-component is about and will have to offer. In the end I am now left with the impression that ICON would have stood a good chance to survive on its own.

Second, as a member of the Imprint consortium I still find it difficult today to sort through this proposal and its various components, tasks, topics, milestones, deliverables etc. Which only tells me how ever so more difficult it must have been for outsiders i.e., reviewers to sift through the bits and pieces and comprehend what this is about. But I also feel that this has to do with the concept of IPs at large as it is not an easy task to compose an IP consortium of the dimension and wide range of expertise envisioned by the commission. The outcome of the whole process in my view confirms the notion that the concept of IPs has fundamentally (and to a large degree predictably) failed. This concept reflects a substantial lack of insight on the side of those who were, presumably still are involved in designing research policies in the commission about what science is about and how it works. Those parties should not be where they are, and they certainly should not be involved in setting up FWP7

This is what I have to say about our proposal.

As for the Commission's performance it is not my impression they are living up to their own standards that they have set up for the quality of proposals requested. In particular the proposal evaluation process is ridiculous and lacks any degree of substance. For instance, the reviews that I did receive in response to my RTN proposal (submitted last year) are mediocre at best, meaningless and useless in detail, beyond anything I would consider expert insight, simply a waste of time and tax payers' money. They are an insult to anybody who did contribute to and put work and effort into that proposal. As for the Imprint proposal we now are faced with the prospect that the only IP proposal, Millennium, that is competing with Imprint from the outset was received more favourably than our own proposal. With this I could live were it not for the fact that in Millennium everything is named as a strategy and work plan that we were

being advised to not do. This speaks a language of its own and to me reflects a fundamental lack of enthusiasm, professionalism and competence with those who give advice and organize the evaluation process.

Obviously,

the vision set out by our programme manager(s) never made it to the reviewers who seemed to follow quite different guidelines, if any.

Lastly, from what I can see around me, particularly in the Mediterranean club, it appears more important and beneficial to spend time in Brussels wiping door handles and leaving a professorial - directorial impression rather than composing upbeat cutting edge science proposals. It is ever so

disheartening that within the FWP our success seems to depend more on who we know than the quality we present. Last time when programme managerial posts in the commission were reshuffled the primary concern around here was

that "we now lose our contacts". This is wrong, a disgrace to our community.

I have had a few conversations with colleagues who were partners in EU proposals, both successful ones and ones that were rejected. From these conversations I sense a growing degree of tiredness about EU science policy

and more so, about the chaotic way proposals are being solicited and then turned down on grounds that so very obviously have nothing to do with the science presented. There is also the notion that within the commission climate and paleo-work has fallen from grace, for reasons not known to many. Which brings me back to the point that perhaps we do not have the right programme managers in place to fend our cause.

I am prepared to write a firm letter to the commission, or to contribute to

such letter, about the issues impinging on the poor performance of the commission. I rather do that before turning entirely into a full-grown Euroseptic.

Subject: [Fwd: RE: commission performance alpha 5]  
Date: Thu, 12 May 2005 04:48:04 +0200 (MEST)

Dear all IMPRINT colleagues,  
Being away from Europe, this was a very bad news that I got this morning listening about the rejection of IMPRINT. Eystein did a great job by being able to gather the European paleo community under a common umbrella and he deserves a lot of our consideration.

Concerning now the review process, I have been involved several times in Brussels and I have been able to see the evolution of the evaluating panel session after session.

I am not please with this evaluation and I already addressed my comments to Andre Berger. It is not normal that entering the room where you are supposed to meet the other "panelists" you would not know those who are supposed to be representative of your community, this is my first comment.

Second, the way the referees are selected is somehow strange and involve a political issue which is very sensitive as I'm sure you will understand that a country fair representation is not enough in our field which better involves expertise.

Third and last, having set a consortium of the leading Europe institutions and scientists, how can you expect appropriate expertise? I have been approached to join the evaluating panel but refused as being an IMPRINT member to respect some ethic. If, what I wish, we all didi that way, they one can sincerely expect the worst as I already experienced in a recent past.

Forth, complaining to the commission is a waste of time as these administrative people, even if this is you right, will always provide you with arguments to justify the decision. I complain once to the director of the programme who just retun me that the referees of my proposal were relevant, what I know was not the case unfortunately. However I totally support the initiative to question the commission on the way the evaluations are performed, but also how the referees are selected.

Fifth, you all are waiting for the reviews. I agree with Rainer that the comments that are provided are useless and in somehow offending the PIs. This is mostly due to the review process and this again must be changed.

Furthermore what we receive is the consensus report which passed in the European officers hands to be cleaned of any aggressive sentences or words, and must remain politically correct. So effectively these reports are useless. It would be interesting to get also the individual reports on which the consensus one has been established and would better show the real work of every referee, and we would be very surprised sometimes.

Finally to follow Thomas, Rainer and Eric, I would suggest to continue what has been launched with IMPRINT which is to my sense unique in gathering all the European paleo community under the same umbrella. May be the proposal was too broad, but this was following the commission's aim. The "Millenium" proposal benefited of several consecutive EU supports which apparently helped a lot. Their lobbying seem to have ben very efficient, not only in Brussels but in the journals and meetings. The Utrecht initiative was a good one which must stop today. We have the opportunity to gather regularly at least once during the EGU that we all are attending, why not using such opportunity to reinforce the initiative during such meeting?

All the very best to all of you

cheers

denis

richard.telford@bjerknes.uib.no Subject: commission performance alpha 5

dear Eystein, dear Imprint consortium,

I am sure I will not make many friends with what follows below. Firstly, it surely is sad and disheartening to see our proposal going down. and there are many issues involved some of which have been named in the recent emails. But then there are those issues left that have not been named but which I consider relevant if we are to make progress on the EU FWP front. Some of these issues may and will touch a personal nerve here and there, but let's face some of the unpleasant realities much rather than sitting back and keeping going with business as usual, a business that soon may go out of existence.

First, I am not convinced that Imprint was the best we could have done. On my side I was surprised to no small extent during our London meeting to see that those from the modeling community and other groups present obviously had no idea why our palaeo-component (a derivative of the planned ICON IP) was part of Imprint, and they were not overly favourable to listen and expand their views. So in a sense, even within our own consortium there was, perhaps still is a lack of insight and understanding as to what a palaeo-component is about and will have to offer. In the end I am now left with the impression that ICON would have stood a good chance to survive on its own.

Second, as a member of the Imprint consortium I still find it difficult

today to sort through this proposal and its various components, tasks, topics, milestones, deliverables etc. Which only tells me how ever so more difficult it must have been for outsiders i.e., reviewers to sift through the bits and pieces and comprehend what this is about. But I also feel that this has to do with the concept of IPs at large as it is not an easy task to compose an IP consortium of the dimension and wide range of expertise envisioned by the commission. The outcome of the whole process in my view confirms the notion that the concept of IPs has fundamentally (and to a large degree predictably) failed. This concept reflects a substantial lack of insight on the side of those who were, presumably still are involved in designing research policies in the commission about what science is about and how it works. Those parties should not be where they are, and they certainly should not be involved in setting up FWP7

This is what I have to say about our proposal.

As for the Commission's performance it is not my impression they are living up to their own standards that they have set up for the quality of proposals requested. In particular the proposal evaluation process is ridiculous and lacks any degree of substance. For instance, the reviews that I did receive in response to my RTN proposal (submitted last year) are mediocre at best, meaningless and useless in detail, beyond anything I would consider expert insight, simply a waste of time and tax payers' money. They are an insult to anybody who did contribute to and put work and effort into that proposal. As for the Imprint proposal we now are faced with the prospect that the only IP proposal, Millennium, that is competing with Imprint from the outset was received more favourably than our own proposal. With this I could live were it not for the fact that in Millennium everything is named as a strategy and work plan that we were being advised to not do. This speaks a language of its own and to me reflects a fundamental lack of enthusiasm, professionalism and competence with those who give advice and organize the evaluation process. Obviously, the vision set out by our programme manager(s) never made it to the reviewers who seemed to follow quite different guidelines, if any.

Lastly, from what I can see around me, particularly in the Mediterranean club, it appears more important and beneficial to spend time in Brussels wiping door handles and leaving a professorial - directorial impression rather than composing upbeat cutting edge science proposals. It is ever so disheartening that within the FWP our success seems to depend more on who we know than the quality we present. Last time when

programme managerial posts in the commission were reshuffled the primary concern around here was that "we now lose our contacts". This is wrong, a disgrace to our community.

I have had a few conversations with colleagues who were partners in EU proposals, both successful ones and ones that were rejected. From these conversations I sense a growing degree of tiredness about EU science policy and more so, about the chaotic way proposals are being solicited and then turned down on grounds that so very obviously have nothing to do with the science presented. There is also the notion that within the commission climate and paleo-work has fallen from grace, for reasons not known to many. Which brings me back to the point that perhaps we do not have the right programme managers in place to fend our cause.

I am prepared to write a firm letter to the commission, or to contribute to such letter, about the issues impinging on the poor performance of the commision. I rather do that before turning entirely into a full-grown Eurosceptic.

Eystein

We have now heard from Hans Brelen that Millennium will definitely be funded . This means that the very worst case scenario has been realised - because it means that the EU are not likely to call for any palaeoclimate in the next funding round.

I have to say that though there is normally an unfortunate element of randomness in the refereeing of EU proposals , that to a large extent is unfortunate but inevitable, I believe strongly that the system has let us down very badly in this case. It is clear that we, the IMPRINT community were misled ; first by Ib Troen's direction (given publicly in Utrecht) that we should produce a proposal which was of the scale to unify the whole Palaeoclimate community , with a specific role to bring data and modelling foci to bear on the issue of climate predictability; that we should be careful to not to over-emphasise the collection of new data but rather work mostly to consolidate and jointly interpret existing data , and that we should formulate a scheme were these fed directly into a hierarchy of modelling that would address model viability and issues of probability of future climate and its causes.

Secondly, We were misled by the accepting , on the basis of the published call, that the EU required IP proposals of ambitious scope , large enough to move the science of European palaeoclimate forward as a whole and with relevance to globally important issues, with aims clearly beyond the scope of "slightly bigger STREPS" . On reading the cursory referees' responses to our proposal , I am also moved to express my own opinion that they are an insult to the community of researchers that constitute IMPRINT , and an indictment of the failure of the referees to address their assessment to the generally publicized aims of the IP concept. To describe the whole proposal as "too complicated", and to state that there is " no value" in the first four workpackages , and most of all to rate the quality of the consortium as 4 out of 5 , all require explicit justification well beyond the few lines with which we are presented.

While I have no ill will at all regarding the competing proposal Millennium , I feel that the extended IMPRINT community can justifiably ask very serious questions regarding the apparent lack of equitable assessment of the two proposals in the light of the published call requirements - the efforts of the IMPRINT consortium over recent months at least deserve answers as to how , for the sake of 0.5 of a mark , that proposal will be funded when it clearly did not address the scope of the original call - in terms of community integration, emphasis on wider data consolidation, scope of model hierarchy, and specific addressing of the data/model integration towards the issue of climate sensitivity/predictability.

Expressing these concerns should not be considered "sour grapes " . They are not and I congratulate the MILLENNIUM team on having succeeded . Rather these comments are justified because the review process has not taken account of the scope of the IP concept, and the need to invoke a research plan with the necessary breadth and expertise (and proven

managerial ability - as can be gauged by the assessment of the CARBO OCEAN coordination plan) , and because the success of the much more limited MILLENNIUM project has already been cited by European officials as justification for the lack of any need to fund palaeoclimate research in the next call - effectively cutting off the wider paleoclimate community from EU research support for the next few years.

I believe we are justified in questioning the operation of the IP concept , beyond the EU administration, which has , in my opinion has done a serious dis-service to our community and palaeoclimate in general.

At 08:26 16/05/2005, Valérie Masson-Delmotte wrote:

Dear Eystein and Keith,

I hope that you had a good trip back from Beijing. On our side it was a bit hectic (3 hours delay in Amsterdam, arrival at midnight in Paris and lost of Pascale's luggage without ability to find where it was lost!).

I have just received this suggestion from a CEA EC representative that there is a RTN Marie Curie call for september 8th which has a lot of funding - 220 Meuros. You can apply for up to 6 M euros for a series of PhD thesis and postdocs around a real research network (up to 3-4 contracts per participant).

I think that it is an excellent idea... if you and your people, Eystein, would be ready to put some more energy in the proposal.

It would require to re think about the scientific perimeter and the key partners maybe.

Sincerely

Valerie.

Cher Jean - Pierre,

Excuse-moi de réagir un peu tardivement (je reviens de Chine).

Mais surtout merci pour ce courrier et l'aide proposée ; je pense vraiment que cela vaudrait le coup de le relancer sous la forme RTN et que l'obtention de post-docs correspond bien à l'idée d'imprint (exploitation des données, modélisation).

Pour faire avancer les choses je mets copie à Valérie Masson - Delmotte une des chevilles ouvrières d'IMPRINT au LSCE. Je suggère à valérie de te contacter directement.

Bien amicalement Jean

Bonjour Jean,

J'ai appris ce matin au GTN environnement qu'IMPRINT n'avait pas été accepté.

Avez-vous pensé à le relancer sous la forme d'un (ou de plusieurs) RTN-Marie Curie (Research Training Network) pour l'appel du 8 septembre qui est richement doté (220 MEuros ! du jamais vu !); le montant demandé peut aller jusqu'à 6 MEuros, pas très loin d'IMPRINT.

Il s'agit de proposer une série de post-docs et de thèses articulés autour d'un véritable projet de recherche; environ 3 à 4 CDD pour chaque participant.

La DSM a une expérience dans ce domaine (Greencycles rien qu'au LSCE); on peut t'aider à te monter un projet taillé sur mesures.

Aujourd'hui je ne vois que cette solution car manifestement la ligne "modélisation climat" ne repassera pas au 4ème appel et je ne vois rien d'autre d'aussi bien "doté" dans le paysage du FP6 (qui est sur sa fin).

Cordialement

JPC

Cher Jean - Pierre,

Excuse-moi de réagir un peu tardivement (je reviens de Chine).

Mais surtout merci pour ce courrier et l'aide proposée ; je pense vraiment que cela vaudrait le coup de le relancer sous la forme RTN et que l'obtention de post-docs correspond bien à l'idée d'imprint (exploitation des données, modélisation).

Pour faire avancer les choses je mets copie à Valérie Masson - Delmotte une des

chevilles ouvrières d'IMPRINT au LSCE. Je suggère à valérie de te contacter directement.

Bien amicalement Jean

Bonjour Jean,

J'ai appris ce matin au GTN environnement qu'IMPRINT n'avait pas été accepté.

Avez-vous pensé à le relancer sous la forme d'un (ou de plusieurs) RTN-Marie Curie (Research Training Network) pour l'appel du 8 septembre qui est richement doté (220 MEuros ! du jamais vu !); le montant demandé peut aller jusqu'à 6 MEuros, pas très loin d'IMPRINT.

Il s'agit de proposer une série de post-docs et de thèses articulés autour d'un véritable projet de recherche; environ 3 à 4 CDD pour chaque participant.

La DSM a une expérience dans ce domaine (Greencycles rien qu'au LSCE); on peut t'aider à te monter un projet taillé sur mesures.

Aujourd'hui je ne vois que cette solution car manifestement la ligne "modélisation climat" ne repassera pas au 4ème appel et je ne vois rien d'autre d'aussi bien "doté" dans le paysage du FP6 (qui est sur sa fin).

Cordialement

JPC

Hi Keith,  
for your information, I have enclosed the letter received on the outcome of phase 1, and the guidance for Stage 2. We will dig up more. I also talked with Christoph Heinze who said this definately has the flair of someone in the review panel having an agenda of revenge, and that this could be an element of a formal complaint.

More later,  
Eystein

Mike,

Just reviewed Caspar's paper with Wahl for Climatic Change. Looks pretty good. Almost reproduced your series and shows where MM have gone wrong. Should keep them quiet for a while. Also they release all the data and the R software. Presume you know all about this. Should make Keith's life in Ch 6 easy !

Also, confidentially for a few weeks, Christy and Spencer have admitted at the Chicago CCSP meeting that their 2LT record is wrong !! They used the wrong sign for the diurnal correction ! Series now warms - not quite as much as the surface but within error bands. Between you and me, we'll be going with RSS in Ch 3 and there will be no discrepancy with the surface and the models. Should make Ch 3 a doddle now ! Keep quiet about this until Bern at least. Can tell you more then. RSS (Carl Mears and Frank Wentz) found the mistake !

The skeptic pillars are tumbling !

Cheers

Phil

Dear friends of the Imprint - SSC,

After seeing the evaluation summary of our proposal, and not least the same for Millennium, it is clear to me that we have been very badly treated, first by the public advice from the Commission in Utrecht who advised the community to create a proposal which we did, but which is orthogonal to what they now have decided to negotiate, later by the random way we were reviewed and the many inconsistencies in the evaluation. Compared to this the Millennium review was full of subjective phrases and a number of negative aspects were glossed over. The review is an insult, and it appears likely that elements in the panel bear some grudges against our community. In order to get the 0.5 point difference between Imprint and Millennium they had to give a number of very imbalanced statements. They also had to raise the management score of Millennium to 4 by the xtended panel despite criticisms by the reviewers that the management was not well laid out.

I feel that the review was very biased and the result is that they will probably fund a project with only limited relevance to the call, and miss a major opportunity of integrating European paleoclimate research and climate modelling and create a new major step forward.

We have been advised to send a formal letter of complaint to the Commission, asking for a renewed evaluation, not because we think there is a good chance that it will lead to much, but we think it

is important that they know that they have upset a community consisting of top level European scientists, This may help us in the longer term.

The advice I have got is to send this to Pierre Valette, co-signed by the key partners, both their PIs and head of administration, with copies to our individual national members of the Global Change Panel of the EU.

So far there is no formal decision on which proposal to fund, this may happen in September after negotiations with the selected proposals. There is a seldom precedence in Europe that such an intervention has been successful, but very rarely.

In phrasing such a letter we have to be very careful and make sure our message is clear and fair, but I think it needs to be done.

I would therefore ask you to respond immediately to this mail as to whether you think we should go this route or not. We will then in a few days send out a draft for comments, if you agree that we shall send in a complaint. We have to move fast here, so I hope you will be quick.

Concerning the other proposals on what to do, there are many good ideas, and I think we should have a meeting in the autumn to discuss the strategy of securing paleo in the 7th Framwork program. The text is out for review now, and we all need to suggest changes through our national representatives. I will distribute a list of who this is for the various countries over the week-end.

I am also working on formulating text to help launch our ideas in teh European Parliament via Atte´s wife.

Best wishes,

Eystein

<x-flowed>

Hi Keith - thanks again for the help in Beijing. We hope you found a fabulous clay pot or at least some good views of China.

We know it's going to be extra hard on you to get everything done on time, but we're hoping you can more-or-less stick to the schedule we just sent around. Your section is going to be the big one, and we need to make sure we have as much review and polishing as possible. If we don't we (especially you) will pay heavily at FOD review time. Lots of work now saves even more work later. Or so the real veterans tell us.

Lastly, we wanted you to know that we can probably win another page or two (total, including figs and refs) if you end up needing it. Susan didn't promise this, but she gave us the feeling that we could get it if we ask - but probably only for your section, and maybe an extra page for general refs (although we're not going to mention this to the others, since we're not sure we can get it). Note that some of the methodological parts of your sections should go into supplemental material - this has to be written just as carefully, but it gives you another space buffer. All this means you can do a good job on figures, rather than the bare minimum. We're hoping you guys can generate something compelling enough for the TS and SPM - something that will replace the hockey-stick with something even more compelling.

Anyhow, thanks in advance for what is most likely not going to be your number 1 summer to remember. That said, what we produce should provide real satisfaction.

Best, Peck and Eystein

Kevin,

I'll broach it with the UK people. Need to consider timing in November, once we get the comments or maybe after the ChCh meeting. Been to Boulder in Jan and Feb before so know what to expect ! Early Feb would seem best. Not thought about going to the AMS so won't.

A few problems with Figures today. Hopefully they will get resolved in the not too distant future. Dave E has at least sent one email.

Seeing our granddaughter on Saturday, but should have some good time for the Chapter on Sunday and Monday (at home).

Cheers

Phil

At 17:11 25/05/2005, you wrote:

Hi Phil

I am attaching the updated Fig 3.4.? I have also in .ps that can be converted if need be.

Dennis has also plotted the Fu data and I'll send a version a bit later. But need to have consistent colors.

I am encouraged that the text is getting a lot better. The FOD is approaching close to what will be final, we should find. After that point the figs should only be updates and minor changes, and the text is modified to respond to comments, that we will have to address more systematically next time. The SOD does become close to final: still subject to all the reviews and late breaking material.

Key thing is for you and me to make sure we converge, and don't do a wholesale replacement of a section without careful checking.

I have decided not to attend AMS AGM next year in January so that I can work on the SOD. I would be glad to invite you to come for a visit for a week and I suspect we can also come up with some funds to help: at the price of a seminar. e.g. we could split it by you doing airfare and we do local accommodation or vice versa? This summer Tom Stocker is here and working with Jerry on chap 10. I think it could be worthwhile, main question is best timing. Perhaps late Jan or early Feb? That time of year can be cold here: usually not that much snow or if it does snow it does not last long in Boulder: great skiing nearby if you are interested in that. Mean T in Jan is about 0C but highs not uncommon about 10C, and have been over 20C with chinook. Cold at night. So good idea.

Cheers

Kevin

Phil Jones wrote:

Kevin,

Things seem to be coming in. Will work on 3.5-3.7 tomorrow. 3.2 and the Appendices now back with David. The Appendices read pretty good - lots of useful background material. It will be shame to lose it to a web site. Once David gets these back these should be almost good enough to go out to all on July 15 (or whenever we said).

A thought kept recurring - there must be a better way to do this ! Although the FOD reviews will be different from the ZOD (and many more), I'm prepared to come to Boulder for a week

in early 2006 if needed. I think I can get the money from the UK to do this. Question is

will be it be worthwhile. Better if we were both locked away somewhere other than one of our institutions, but then we wouldn't have the infrastructure, support (email, printers etc).

Anyway, give it some thought. You'll know more than I do about some much the FOD and SOD change. Q is whether a week or a fortnight is sufficient. If we knew that a few of the

key people in the chapter were at their desks, the text should show a marked improvement.

Assuming here the majority of the Figures set by then - just a few need updating.

Cheers

Phil

At 17:03 24/05/2005, you wrote:

Hi Phil

Thanks for update: monday is a holiday here: Memorial Day, seems weird that Brian is working?

My approach to the revisions at this stage is not to take the material sent and wholesale replace it, but cautiously compare and insert if it makes sense. i.e. you and I need to act as editors with a fairly strong hand. I suspect 3.7 may have some useful material but it could degrade the section by further adding material that is not especially relevant. I'll bet it does not shorten it, which is desired still.

I am clearly not on same page as Brian wrt clouds and radiation, and I am interested in his take on it all, given the new material and changes. I am not a fan of Norris' stuff. We have updated Fig 3.4.1 on water vapor thru 2004: the ocean trend drops to 1.2%/decade. So you can help a lot by putting your take on the 3.4 stuff: it may also require some careful wording to accommodate different views if we can't see eye to eye. For instance, on the dimming, the recent Pinker paper uses ISCCP and I simply don't believe the trends from ISCCP at all. Saying Wielicki and ISCCP agree actually damns them both. Or similarly saying Norris and ISCCP agree causes problems (this relates to upper cloud, which Norris gets from total minus lower, but those two sets of data are

not homogeneous: there is not a lower cloud ob for every total; using means, esp zonal means without differencing each ob potentially causes major problems).

Dennis is starting on the 3.6 figs today plus the Sahel one.

Cheers

Kevin

Dave,

Thanks for the update on the maps. Can you calculate a CRU time series from what you have? Exactly which dataset do you have? Is it CRU TS 2.0? If this is it then OK. This is the infilled one, so variance may be a little low in early years. Hopefully your calculations will agree with Aiguo. I don't have anyone here to do this at the moment. There seem a lot of deadlines at the moment here, which is making it hard for me to find quality time for Ch3. Luckily there is a holiday weekend coming up and I hope to use that to get 3.5-3.7 looked over. 3.2 is now done and agreed with David. I'll tweak anything when I get your spatial maps. I came in with good intentions today, but have been answering emails and seeing students.

As for smoothing, we didn't agree. For temperature we are going with the HC 'approximate' 20-year binomial. I'll attach a figure David's produced to let you see that. I reckon if you did a 13-year binomial you'll get something like it. Remember to send David all the series for trend estimation when you have them.

I am assuming Bin Wang did 3.7.1. Can you clarify with Dave exactly what 3.7.1 is? Give him the method to calculate it. Also clarify the two Chen's.

I see that David has emailed his reading of the English. I was about to wright something like this. It is definitely the difference between two period averages and not extremes years in the periods. The caption obviously needs a lot of work - I'll have a go at that when I get to it.

If the 3 of us are having difficulties, what hope have we for the readers. If you can't get anything remotely like it I would suggest we drop it - but try David's English translation first !

Cheers  
Phil

At 14:11 26/05/2005, David Easterling wrote:

Phil,  
We will have the maps redone next week and I have started reworking the text for 3.3 Do you have a CRU global pcp time series for 1901-2003 you can send or should we calculate? I have the numbers for the figure Aiguo Dai sent. Also, we never decided on a standard smoothing routine. My preference is for a 13 or 9 point binomial with reflected ends, but we need to decide.

Last, it is still not clear who did figure 3.7.1, was it Bin Wang? The two Chen papers are by different authors, the 2004 EA monsoon paper is by T-C Chen of Iowa State U., and the 2002 paper and data set creator is Ming Chen at NOAA/CPC. I have requested the PREC/L data set from CPC. But I am not even sure exactly what 3.7.1 is, the title says change in mean annual range between the two periods, which I interpret to mean the difference between the highest and lowest years for the post 1976 period minus the difference between the highest and lowest from the pre-1976 period giving a measure of change in year to year consistency of monsoons. Also, there is a reference in the text that Chen et al. (2004) compiled PREC/L, but that is not the case, it should be Chen et al. (2002) as creator, but with an update to 2003.

Dave

Phil Jones wrote:

Dave,

I still don't understand why Bin Wang is involved in this ! Have you contacted Chen? Maybe it was Bin Wang. Have you looked into trying to reproduce it?

Panmao has sent me a revised 3.7.3 using HadSLP2. I'm going to contact Rob Allan about this one as he's been involved in developing HadSLP2.

Will you be in a position to send revised Figures soon? Any date also when you'll be working on the text of 3.3?

Cheers

Phil

At 19:44 25/05/2005, David Easterling wrote:

Phil,

I am trying to track down the source of Fig. 3.7.1 the epoch difference in monsoon rainfall map. It has a reference of Chen et al. 2004, which is the J. Climate paper on the east Asian monsoon, but this figure is not in the paper.

Someone must

of plotted it using their data, but not sure who. Do you know?

Dave

<x-flowed>  
Dear Olga,

I deeply apologize for having not read your e-mail earlier. I was so overburdened with other obligations when coming back from Beijing that I gave myself the deadline of June 1 to start with IPCC work. As usual, circumstances have forced me to postpone this "deadline" to next Monday. For this, I had not realized that Chapter 6 has its first deadline tomorrow. I have now gone through the "Glaciers during the LIA" and "Glaciers during the MWP" paragraphs as well as through the "glacier bullet" you send today.

I think the LIA paragraph fits well into the Chapter 4 as a supplement to the "Observations" we concentrate on. The MWP is a bit out of focus (Observations!). As I mentioned earlier, I would be glad if chapter 6 could give glaciers appropriate space as being the only climate proxies which are exclusively governed by physical processes and are, thus, much safer to interpret than any other proxies. The fact that they give filtered information as a mean over longer time periods enables them to represent climate. Over the last years, glaciologists have started to investigate the impact of climate seasonality on glaciers and have also started to separate thermal and hygric variables driving glaciers. All this deserves much attention also beyond the "Observations" to be covered in Chapter 4.

A comment on the bullet: this is fine. The only point I would change is the one mentioning Africa. For Lewis Glacier, Mount Kenya, advances have been reconstructed from moraines around 1900 and (measured) thickening took place in the 1970s. Rwenzori glaciers have advanced in the late 1960s and early 1970s. A compilation of this is attached as well as a figure and a table from an ongoing compilation of the post-LIA retreat of tropical glaciers I am working on. Please keep them confidential. Note from this figure also the exception Kilimanjaro glaciers play. They have to be seen separately from anything else we observe in the tropics mainly because of the absolute lack of movement on the Plateau (there are also other reasons which would go beyond a readable e-mail). So, to make the long story short: (i) African glaciers are no exception to the global picture and (ii) Kilimanjaro glaciers are an exception in Africa, in the Tropics, and on the global picture. Thus, Kili glaciers should not be used as an example neither for Africa nor for the tropics. Although I am highly interested in Kilimanjaro myself running a research project there, I

strongly suggest to not overestimate its glaciers. According to a request from Susan Solomon I will address that briefly in Chapter 4.5. By the way, Kili glaciers only cover 2.6 km<sup>2</sup> out of 2,500 km<sup>2</sup> in the tropics (see table in attachment).

Hope this is of help and if you have any further question feel free to contact me. Best wishes, Georg

Eystein

tried phoning on your mobile - no luck - Don't like this Figure , but still having trouble working on ours. Have cut large bits out of my text and suggestions for cutting other bits , but will be a little late sending these bits. Can you ring to discuss (and IMPRINT) tomorrow ?

Keith

Hello,

I have been fiddling with the best way to illustrate the stable nature of the medieval warm period - the attached plot has eight sites that go from 946-1960 in decadal std. dev. units - although small in number there is a good geographic spread -- four are from the w. hemisphere, four from the east. I also plot the raw composite of the eight sites and scale it to the 30-90N decadal temp. record.

this record illustrates how the individual sites are related to the composite and also why the composite has no dramatically warm MWP -- there is no dramatically warm clustering of the individual sites.

use or lose as you wish, tom

Mike,

I will reply to Yasmine and say no tomorrow. Don't want to do it too soon. Keith and I and Tim have been having loads of discussions about Ch 6 for IPCC. Keith has to submit his latest draft tomorrow for better for worse. What I'm thinking is that sometime when the three of us here have some spare time - which may be some ways off, we'd like to do some experiments with different proxy combinations. Would you be happy sending us all the proxies you have (or Scott - the rookie) is putting together? If so can you arrange it. There is no rush. We won't pass any on or put on web sites etc. If we ever did get some time then we could do something - it will be slowly, not for this IPCC and unlikely to get written up or started until well into 2006.

Cheers  
Phil

Anders,

Sending again. Your server rejected this because of the extensions so changed them. Hoep you get them.

Phil

Anders,

Thanks for the files. I was aware that the EGU was starting a new paleo journal. I don't think there have been any issues yet.

I thought Keith had put those two series on our web site, but I can't find them either. However, I found them ages and put them with some of the other long tree-ring series. So here they are with others.

The ones you want should be in columns 1 and 2. The file starts in 1628BC, so it takes a while to get to them. They start in AD 500. I vaguely recall chopping off the 402-499 and 441-499 years because of sample size. Keith has more trw series now, so they could be improved. Keith should have a reconstruction from the Grudd et al. (2002) paper in The Holocene, but they must be on his machine.

I hope the papers for the two Fennoscandian series tell you what the base period is. Given the publication dates I would suspect it is 1951-80.

There are newer series for Jasper and Tasmania and I wouldn't bother doing anything with the two South American series.

Have a good summer break. Ruth and I have sat out every night this week so far. We watched birds the last two days denuding the cherry tree of cherries.

Cheers

Phil

At 07:52 23/06/2005, you wrote:

Phil,

Here are the data we used in our Nature paper, minus Indigirka and Lauritzen. All series are interpolated to annual resolution. Brief info in file headers. The details are found in the online supplementary info on nature.com

Lauritzen's email:

"S. E. Lauritzen" <stein.lauritzen@geo.uib.no>

The Finnish diatom series and all eastern tree ring series have been sent through personal contacts. The rest comes from the web, apart from GRIP which comes from you. Could you, in return, send me the data file for the Fennoscandian summer temperature reconstruction from either Briffa et al (Nature 1990) or Briffa et al (Clim Dyn 1992) - or both? I could not find any of these series on the CRU website.

I realize that Isabelle Gouirand will have to discuss these two papers. Starting from there and try to point out something new as regards the work done by Isabelle. By the way, do you know anything about this journal:

[1] <http://www.copernicus.org/EGU/cp/cp.html> ? I did not know it existed, before I was told about it yesterday.

Tomorrow starts my summer holidays, which last over the coming four weeks

Cheers,

Anders

Hi gang - I still have to weigh in on the great figs/text that Keith and Tim have created, but here's some feedback in the meantime.

I agree that a mean recon isn't the thing to do. Let me think more before I weigh in more on the fig. Working to get other LAs to get their stuff in.

As for the Southern Hem temperature change fig (and caption and a little text), I agree that you (Ricardo in the lead) should do it as you've proposed. We need a clear S. Hem statement, and although it should stress that the data are too few to create a reliable S Hem recon, we should show the data that are available. Thus, PLEASE proceed Ricardo on this tack. Also, can we include the borehole recon series from S. Africa and Australia (e.g., Pollack and Huang, 98)? I'm sure Henry Pollack would provide fast - cc Huang too, since he might be even faster. Keith and Tim, does that make sense?

Please note that I think we can find room for the above, regardless, if it is compelling enough.

As for ENSO, we will need to address for sure - based mainly on the more direct coral data rather than teleconnected (e.g., tree-ring) relationships. The latter don't seem to be definitive enough at this time - as I think we discussed in China. The same holds true for NAO/AO/PDO etc., and I think that we (Keith and Tim) will need to have this in their section - in an appropriately short manner. I'll provide more feedback on this soon, so don't sweat it for now.

Main thing is to go ahead on the S Hem temp fig/caption/short text., independent of ENSO etc discussions.

Thanks, Peck

Cc: Eystein Jansen <eystein.jansen@geo.uib.no>

<x-flowed>

Hi Keith and Tim - Eystein is going to chat with you tomorrow, and my goal is to get as much as I can to you guys today and tomorrow.

First, off the figures are great (!) - that was tough job, and I'm very impressed. Of course, I can already start to sense what the debates will be, but we can address that in the text. Here are some comments with respect to the figures - some are relevant to the text...

- 1) they really are great
- 2) is the instrumental series on the first fig (top and bottom) the same as featured in chapter 3? Need to say that.
- 3) rather than clogging up the caption with all the notes on each curve, how about a table for each of the two figures. Then you can include some more info on each recon - e.g., number of sites, types of proxies??) I'm thinking mainly that the captions are not pretty, but you may be able to include more summary info on each curve also
- 4) should we make all the series in their original and modified for the figure form available on a www site so that reviewers can play with the data and make sure they get their two cents in before this thing is all said and published? The WDC-A is ready to help w/ posting of data and figs (see below).
- 5) I like the expanding time axis, but I'd be prepared to have a second one with a linear axis. In fact, I'd put it up on the www page at the same time with the data. The more we do to help others understand, the better?
- 6) Also, it would be good to see both the data and the figure w/o the Gaussian-weighted filtering. What do these look like, can we make them available as suggested above. At the least, I'd like to see the fig w/o the filtering, even though I know it will be a mess. How

about a series of time series plots (same x and y axes as the big fig 1) - in each you show both the filtered and unfiltered series. I know this is a pain for Tim, but we really have to make sure we're not missing anything in the data. And also - that we anticipate what others will do, ask us to do, or squawk about.

7) On the forcing fig (fig 2) - why don't we see all the different experiment curves (e.g., dotted red) in the forcing plots a, b and c? Need to say why in the caption - and if they have the same forcing, so you can't see it on the plot, need to say it. This could be much easier in a table that indicates "same as X").

8) On fig 2 - does the recalculated envelop of reconstructed temps also include instrumental temps? Think so, but you should say it in the caption. Why doesn't the envelop go up to present? Can it? Might look better, and be more consistent w/ fig 1. If the envelop can't go to present, then maybe include the instrumental curve as in Fig 1.

9) reminders for the text (I'll think about these as I read a second time for editing) -

9a) need to explain why the recons don't continue going up w/ instrumental data at the end (post 1990?) - might what to mention something in caption, if you can shift all the other stuff to a table.

9b) there will be lots of discussion (during and post AR4 drafting) about what recon series (Fig 1) should or should not be believed. Thus, I think it is critical for us to same more about each recon - that is to INCLUDE what you wrote in blue, and perhaps to enhance. Need to really convince the reader that while not one recon is alone the truth (and hence Fig 1), they all have important strengths and weaknesses. But, the former outweigh the latter, so we've included them.

9c) I'm sure you saw the recent (to be infamous) Wall Stree Journal editorial - they showed what I think was a IPCC FAR curve - with the good old MWP and LIA etc (Lamb view? - I don't have the FAR w/ me). The way to handle the hocky stick might best be to put it in an historical perspective along with the older IPCC views. First, show your great figs, discuss them and what went into them, and then - after showing the state-of-the-art, discuss how much our understanding and view have changed. In this, simply compare each of the historical views (FAR, SAR, TAR) to the current view, and while

doing so, play down the controversy (s) - especially the hockey stick. The smart folks will realize that that the fluff in the news is just that, but those with a real stake in that debate will hopefully get the point that it doesn't matter...

10) lastly (almost), I'm sorry to ask again, but I still want to know what is wrong with Tom Crowley's latest plot with all the recons shown together back through the Med W Period? I need to send you my edits on the MWP box, but it seem to me that Tom's fig could go in that box - to help make the point that - sorry, guys - the MWP wasn't much compared to the recent GLOBAL warming...

11) lastly (promise) - don't foget that Eystein and I think we can get a page or two extra for your section in the end. This means you can do all the above, and I can help (next) with the modes and extremes sections, and we can get it all in.

Great job!

Thanks, Peck

Subject: the Med Warm Period Box - Peck comments/edits

Date: Mon, 27 Jun 2005 22:14:09 -0600

<x-flowed>

Gentlemen - attached is the ZOD Med Warm Period Box with my edits/comments. I don't see anything sent since then, so hope I'm not editing the wrong thing. In any case, the Box was pretty nice as is, so I only made a few changes. Obviously, some updating w/ new studies is needed. The big issues are two:

1) the recent Wall Street Journal editorial that is creating all the crap in the US actually showed a time series from the IPCC FAR - if you don't have it, or Eystein can't send, I can scan it in (my Republican Dad sends me these things, although he's an increasingly rare breed of moderate Republican). My thought is that it might be worth adding a couple lines documenting how the view of the MWP changed with each assessment and new knowledge. In doing so, it could be made very clear that there is a reason that scientists don't show those old plots anymore. We need to move the debate beyond the FAR, SAR and TAR on this issue!

2) it would be cool to have another figure that made the point about no single synchronous period warmer than late 20th century. This is where I get soft with respect to Tom's plot. If it is published to the extent we need it, and if the composite or large-area average recon is the same as you are showing in your great new Fig 1, then it seems that it would be reasonable to show Tom's fig as part of the Box - just to show the same thing in a different way, and to hammer in one more nail. That said, I'm not sure if my two conditions above are met (I emailed Tom, no response yet - you might have insight), and I believe you just don't like Tom's fig for some - probably good - reason. But, I wanted us to think extra hard about whether there is SOME fig that might work?

That's it for tonight. Will finish editing your main text next work session tomorrow I hope.

Best, Peck

Subject: Re: NEED HELP!

X-UVA-Virus-Scanned: by amavid-new at fork9.mail.virginia.edu

Mike,

There are broader implications of this, so it is important to respond well. It is

a pity you have to be the guinea pig after what you have gone through already, but you have many supporters.

I would not advise a legal route. I think you need to consider this as just another set of referees' comments and respond simply, clearly and directly. On the science side the key point is that the M&M criticisms are unfounded.

Although this may be difficult, remember that this is not really a criticism of you personally, but one aspect of a criticism of the foundations of global warming science by people both inside and outside of Congress who have ulterior motives.

There may, in fact, be an opportunity here. As you know, we suspect that there has been an abuse of the scientific review process at the journal editor level.

The method is to choose reviewers who are sympathetic to the anti-greenhouse view. Recent papers in GRL (including the M&M paper) have clearly not been reviewed by appropriate people. We have a strong suspicion that this is the case, but, of course, no proof because we do not know \*who\* the reviewers of these papers have been. Perhaps now is the time to make this a direct accusation and request (or demand) that this information be made available. In order to properly defend the good science it is essential that the reasons for bad science appearing in the literature be investigated.

The lever here is that the Subcommittee on Oversight and Investigations of the House Committee on Energy and Commerce is suggesting that your papers are bad science and asking (their point 8e) for the identity of people who reviewed your work. In response, it is completely fair and justifiable to point out that it is the papers that criticize your and related work that are bad science, and that, through the Subcommittee you can request the identities of the reviewers of all of these critical papers -- starting with M&M.

When you respond, there are a number of items that require a direct response from you alone. There are also a number of scientific points where you could give a multi-authored response. There are many people who have expertise in this area and familiarity with the scientific issues who I am sure would be willing to join you (I would be happy to do so).

At this stage, however, I would keep the group small. A few others could be added to the original email list nevertheless. I took the liberty of copying your plea and the Subcommittee's letter to Caspar Ammann, primarily because I think he can help with the scientific aspects better than most people. After all, he has been able to follow your method and reproduce your results, he has shown the flaws in M&M's work, he has investigated the bristlecone pine issue, and he has made all his software available on the web.

The others who could be added at this early stage are Ray Bradley and Malcolm Hughes, your 'co-conspirators' -- and perhaps Phil Jones, Keith Briffa and Tim Osborn. I do not know how 'powerful' these alien opinions may be in the present parochial context, but I note that the instigators of all this are Canadians and that the science has no national boundaries. Phil, Keith and Tim are useful because they have demonstrated the flaws in the von Storch work -- which is, I assume, the

Science paper that the Subcommittee's letter refers to.

A word of warning. I would be careful about using other, independent paleo reconstruction work as supporting the MBH reconstructions. I am attaching my version of a comparison of the bulk of these other reconstructions. Although these all show the hockey stick shape, the differences between them prior to 1850 make me very nervous. If I were on the greenhouse deniers' side, I would be inclined to focus on the wide range of paleo results and the differences between them as an argument for dismissing them all.

I attach also a run with MAGICC using central-estimate climate model parameters (DT2x = 2.6 degC, etc. -- see the TAR), and forcings used by Caspar in the runs with paleo-CSM. I have another Figure somewhere that compares MAGICC with paleo-CSM. The agreement is nearly perfect (given that CSM has internally generated noise while MAGICC is pure signal). The support for the hockey stick is not just the paleo reconstructions, but also the model results. If one takes the best estimates of past forcing off the shelf, then the model results show the hockey stick shape. No tuning or fudging here; this is a totally independent analysis, and critics of the paleo data, if they disbelieve these data, have to explain why models get the same result.

Of course, von Storch's model results do not show such good century timescale agreement, but this is because he uses silly forcing and has failed to account for the fact that his model was not in equilibrium at the start of the run (the subject of Tim Osborn et al.'s submitted paper).

This is a pain in the but, but it will all work out well in the end (unintentional pun

--

sorry). Good science will prevail.

Best wishes,

Tom.

Hi Keith - might be worth talking on the phone - you, me and Eystein - after you get back. You could be right, but it is a powerful way to look at the issue. The question is whether the normalization could be preventing a warmer than late-20th century signal from appearing?

Should we instead update the Bradley Science graphic? That's not as effective in my opinion.

So, let's talk next week?

Going to a tree day meeting or a three day meeting - it has to be tough looking at tree data all day.

have fun, thx, peck

Subject: Re: [Wg1-ar4-ch06] abrupt and Important thoughts on References  
Date: Tue, 28 Jun 2005 23:13:56 +0200

<x-flowed>

Hi all,

Two things:

1. Concerning the 1470k pacing of DO-events. There are revisions underway in the layer-counting of the Greenland Ice Cores. A meeting in Copenhagen in August co-ordinated by Sigfus Johnsen will discuss the issue at length, but there may not be many papers out from the meeting that are citeable for IPCC. There is already the Shackleton paper which indicate that Greenland Ice Cores in MIS3 have an age model that are off by some millennia, and the preliminary data on the new age models indicate substantial revisions as far as I hear from talks given at various meetings. My thinking is that we neither can ignore the fact that current data indicate a 1470 pacing for some time interval of the ice cores if one apply the existing age scales. I think it would be foolish not to refer to it, I think the possibility that the system has the ability to enter into specific cycles is intriguing, and is a result that is well known and IPCC should not pretend we haven't heard about it. But we should make it less blunt than in the current version of the Abrupt Change subchapter, perhaps stating that the result is highly dependant on age models and we need time to absorb new research in order to verify the result.

2. Having the fortune of not being that close to the darker sides of US politics, I have the feeling that Peck's comment concerning referencing perhaps is a bit too "paranoic". I

think the advice is well taken not to overcite our own research, and make sure not to overlook other important contributions, but we should do our best to cite what we think are key results. In any case we will have the FOD review and have the opportunity to have all our good colleagues keeping us honest on this issue.

Cheers,  
Eystein

>Hi all - thanks Fortunat and Stefan for more

Dear Keith,

I have read your text - despite of the heat wave here (40°C in my office in the afternoon...). I am a bit puzzled by the regional aspects. I think that you should make more clear in the beginning that there is very little new information / work conducted on the S Hemisphere / tropics and that most efforts have been focussed on the N Hemisphere, because you mention almost nothing for the S Hemisphere. Is ENSO considered as a regional mode of variability? I thought that it had almost global relevance at least in terms of impacts.

Valérie.

Hi Caspar and Gene - Thanks. I look forward to hearing how things go  
- if the paper is in press by the first week of August, we'll cite it  
in the Chapter 6 of the FOD, but otherwise I guess it'll have to wait  
- that's ok too.

But... keep us posted (and send revised preprint when possible). Thanks! Peck

Hi Gene - good to hear from you. What you list below seems like it must be pretty good to me. Of course, we'd like to include all we can in the FOD, hence the interest in knowing if it's in press or not before the end of the month.

Just keep us updated, and if you feel comfortable sharing the ms. that'd be great, but only if you feel ok about sharing it. The key people are me, Eystein Jansen and Keith Briffa - we won't share it with others.

Thanks for keeping us up to date. Best, peck

From: Phil Jones <p.jones@uea.ac.uk>  
To: John Christy <john.christy@nsstc.uah.edu>  
Subject: This and that  
Date: Tue Jul 5 15:51:55 2005

John,

There has been some email traffic in the last few days to a week - quite a bit really, only a small part about MSU. The main part has been one of your House subcommittees wanting Mike Mann and others and IPCC to respond on how they produced their reconstructions and how IPCC produced their report.

In case you want to look at this see later in the email !

Also this load of rubbish !

This is from an Australian at BMRC (not Neville Nicholls). It began from the attached article. What an idiot. The scientific community would come down on me in no uncertain terms if I said the world had cooled from 1998. OK it has but it is only 7 years of data and it isn't statistically significant.

The Australian also alerted me to this blogging ! I think this is the term ! Luckily

I don't live in Australia.

[1]<http://mustelid.blogspot.com/2005/06/first-look-at-scs-msu-vn52.html>

Unlike the UK, the public in Australia is very very naïve about climate change, mostly because of our governments Kyoto stance, and because there is a proliferation of people with no climate knowledge at all that are prepared to do the gov bidding. Hence the general populace is at best confused, and at worst, antagonistic about climate change - for instance, at a recent rural meeting on drought, attended by politicians and around 2000 farmers, a Qld colleague - Dr Roger Stone - spoke about drought from a climatologist point of view, and suggested that climate change may be playing a role in Australias continuing drought+water problem. He was booed and heckled (and unfortunately some politicians applauded when this happened) - that's what we're dealing with due to columists such as the one I sent to you.

Now to your email. I have seen the latest Mears and Wentz paper (to Science), but am not reviewing it, thank goodness. I am reviewing a couple of papers on extremes, so that I can refer to them in the chapter for AR4. Somewhat circular, but I kept to my usual standards.

The Hadley Centre are working on the day/night issue with sondes, but there are

a lot of problems as there are very few sites in the tropics with both and where both can be distinguished. My own view is that the sondes are overdoing the cooling wrt MSU4 in the lower stratosphere, and some of this likely (IPCC definition) affects the upper troposphere as well. Sondes are a mess and the fact you get agreement with some of them is miraculous. Have you looked at individual sondes, rather than averages - particularly tropical ones? LKS is good, but the RATPAC update less so.

As for being on the latest VG analysis, Kostya wanted it to use the surface data. I thought the model comparisons were a useful aside, so agreed. Ben sent me a paper he's submitted with lots of model comparisons that I also thought a useful addition to the subject.

As for resolving all this (as opposed to the dogfight) I'm hoping that CCSP will come up with something - a compromise. I might be naive in this respect. I hope you are still emailing and talking to Carl and Frank. How is CCSP going? Are you still on schedule for end of August for your open review?

What will be interesting is to see how IPCC pans out, as we've been told we can't use any article that hasn't been submitted by May 31. This date isn't binding, but Aug 12 is a little more as this is when we must submit our next draft - the one everybody will be able to get access to and comment upon. The science isn't going to stop from now until AR4 comes out in early 2007, so we are going to have to add in relevant new and important papers. I hope it is up to us to decide what is important and new. So, unless you get something to me soon, it won't be in this version. It shouldn't matter though, as it will be ridiculous to keep later drafts without it. We will be open to criticism though with what we do add in subsequent drafts. Someone is going to check the final version and the Aug 12 draft. This is partly why I've sent you the rest of this email. IPCC, me and whoever will get accused of being political, whatever we do. As you know, I'm not political. If anything, I would like to see the climate change happen, so the science could be proved right, regardless of the consequences. This isn't being political, it is being selfish.

Cheers

Phil

IPCC stuff ---- just for interest !!!

**IPCC ASKED TO COME CLEAN OVER CONTROVERSIAL HOCKEY STICK STUDIES**

The Committee on Energy and Commerce, 23 June 2005

[2][http://energycommerce.house.gov/108/Letters/062305\\_Pachauri.pdf](http://energycommerce.house.gov/108/Letters/062305_Pachauri.pdf)

Joe Barton, Chairman

U.S. House of Representatives

June 23, 2005

To: Dr. Rajendra K. Pachauri  
Chairman  
Intergovernmental Panel on Climate Change  
C/O IPCC Secretariat  
World Meteorological Organization  
7 bis Avenue de La Paix  
C.P. 2300  
Ch- 1211 Geneva 2 Switzerland

Dear Chairman Pachauri:

Questions have been raised, according to a February 14, 2005 article in The Wall Street Journal, about the significance of methodological flaws and data errors in studies by Dr. Michael Mann and co-authors of the historical record of temperatures and climate change. We understand that these studies of temperature proxies (tree rings, ice cores, corals, etc.) formed the basis for a new finding in the 2001 United Nation's Intergovernmental Panel on Climate Change (IPCC) Third Assessment Report (TAR). This finding - that the increase in 20th century northern hemisphere temperatures is "likely to have been the largest of any century during the past 1,000 years" and that the "1990s was the warmest decade and 1998 the warmest year" - has since been referenced widely and has become a prominent feature of the public debate surrounding climate change policy.

However, in recent peer-reviewed articles in Science, Geophysical Research Letters, Energy & Environment, among others, researchers question the results of this work. As these researchers find, based on the available information, the conclusions concerning temperature

histories - and hence whether warming in the 20th century is actually unprecedented - cannot be

supported by the Mann et. al. studies. In addition, we understand from the February 14 Journal

and these other reports that researchers have failed to replicate the findings of these studies, in part because of problems with the underlying data and the calculations used to reach the conclusions. Questions have also been raised concerning the sharing and dissemination of the data and methods used to perform the studies. For example, according to the January 2005

Energy & Environment, the information necessary to replicate the analyses in the studies has not been made fully available to researchers upon request.

The concerns surrounding these studies reflect upon the quality and transparency of federally

funded research and of the IPCC review process - two matters of particular interest to the Committee. For example, one concern relates to whether IPCC review has been sufficiently robust

and independent. We understand that Dr. Michael Mann, the lead author of the studies in question, was also a lead author of the IPCC chapter that assessed and reported this very same work, and that two co-authors of the studies were also contributing authors to the same chapter. Given the prominence these studies were accorded in the IPCC TAR, we seek to

learn more about the facts and circumstances that led to acceptance and prominent use of this work in the IPCC TAR and to understand what this controversy indicates about the data quality of key IPCC studies.

In light of the Committee's jurisdiction over energy policy and certain environmental issues

in the U.S. House of Representatives, the Committee must have full and accurate information when considering matters relating to climate change policy. We open this review because the dispute surrounding these studies bears directly on important questions about the federally funded work upon which climate studies rely and the quality and transparency of analyses used

to support the IPCC assessment process. With the IPCC currently working to produce a fourth assessment report, addressing questions of quality and transparency in the underlying analyses

supporting that assessment, both scientific and economic, are of utmost importance if Congress

is eventually going to make policy decisions drawing from this work.

To assist us as we begin this review, and pursuant to Rules X and XI of the U.S. House of Representatives, please provide the following information requested below on or before July 11,

2005:

1. Explain the IPCC process for preparing and writing its assessment reports, including, but

not limited to: (a) how referenced studies are reviewed and assessed by the relevant Working Group; (b) the steps taken by lead authors, reviewers, and others to ensure the data underlying the studies forming the basis for key findings - particularly proxy and temperature data - are accurate and up to date; and (c) the IPCC requirements governing the quality of data used in reports.

2. What specifically did IPCC do to check the quality of the Mann et. al. studies and underlying data, cited in the TAR? Did IPCC seek to ensure the studies could be replicated?

3. What is your position with regard to: (a) the recent challenges to the quality of the Mann et. al. data, (b) related questions surrounding the sharing of methods and research for others to test the validity of these studies, and (c) what this controversy indicates about the data quality of key IPCC studies?

4. What did IPCC do to ensure the quality of data for other prominent historical temperature or proxy studies cited in the IPCC, including the Folland et. al. and Jones et. al. studies that were sources for the graphic accompanying the Mann et. al. graphic in the Summary for Policy Makers? Are the data and methodologies for such works complete and available for other researchers to test and replicate?

5. Explain (a) the facts and circumstances by which Dr. Michael Mann served as a lead author of the very chapter that prominently featured his work and (b) by which his work

became a finding and graphical feature of the TAR Summary for Policymakers.

6. Explain (a) how IPCC ensures objectivity and independence among section contributors and reviewers, (b) how they are chosen, and (c) how the chapters, summaries, and the full report are approved and what any such approval signifies about the quality and acceptance of particular research therein.

7. Identify the people who wrote and reviewed the historical temperature-record portions of the TAR, particularly Section 2.3, "Is the Recent Warming Unusual?" and explain all their roles in the preparation of the TAR, including, but not limited to, the specific roles in the writing and review process.

8. Given the questions about Mann et. al. data, has the Working Group I or the IPCC made any changes to specific procedures or policies, including policies for checking the quality of data, for the forthcoming Fourth Assessment Report? If so, explain in detail any such changes, and why they were made.

9. Does the IPCC or Working Group I have policies or procedures regarding the disclosure and dissemination of scientific data referenced in the reports? If so, explain in detail any such policies and what happens when they are violated.

Thank you for your assistance. If you have any questions, please contact Peter Spencer of the Majority Committee staff at (202) 226-2424.

Sincerely,

Joe Barton Chairman Chairman

Ed Whitfield

Subject: RE: Misc  
Date: Wed Jul 6 15:07:45 2005

Neville,

Mike's response could do with a little work, but as you say he's got the tone almost dead on. I hope I don't get a call from congress ! I'm hoping that no-one there realizes I have a US DoE grant and have had this (with Tom W.) for the last 25 years.

I'll send on one other email received for interest.

Cheers

Phil

At 14:21 06/07/2005, you wrote:

Thanks Phil.

I had seen the estimates of 0.12C for UAH 5.2, but wasn't sure if the version producing these trends had all the months corrected, and that John was happy with the corrections (I had heard that his initial estimate was that the change made a major difference to the trends, but that later calculations didn't support this). I think I have a pretty good idea now of the trends in the various data sets.

I have seen the Mears/Wentz paper, but will watch out for John's paper (I know I could have asked John about all of this, but I suspect he feels a bit over-burdened and harrassed at the moment, and I didn't want to add to the pressure on him, so thanks for passing this stuff on to me).

I thought Mike Mann's draft response was pretty good - I had expected something more vigorous, but I think he has got the "tone" pretty right. Do you expect to get a call from Congress?

Subject: Fwd: Misc

Neville,

Here's an email from John, with the trend from his latest version

in. Also

has trends for RATPAC and HadAT2. If you can stress in your talks that it is more likely the sondes are wrong - at least as a group. Some may be OK individually. The tropical ones are the key, but it is these that least

is know

about except for a few regions. The sondes clearly show too much cooling in the stratosphere (when compared to MSU4), and I reckon this must also affect their upper troposphere trends as well. So, John may be putting too much faith in them wrt agreement with UAH.

Happy for you to use the figure, if you don't pass on to anyone else.

Watch

out for Science though and the Mears/Wentz paper if it ever comes out.

Also, do point out that looking at surface trends from 1998 isn't very clever.

Cheers

Phil

Kevin,

In the caption to Fig 3.6.2, can you change 1882-2004 to 1866-2004 and add a reference to Konnen (with umlaut over the o) et al. (1998). Reference is in the list. Dennis must have picked up the MSLP file from our web site, that has the early pre-1882 data in. These are fine as from 1869 they are Darwin, with the few missing months (and 1866-68) infilled by regression with Jakarta. This regression is very good ( $r > 0.8$ ). Much better than the infilling of Tahiti, which is said in the text to be less reliable before 1935, which I agree with.

Cheers  
Phil

<x-flowed>

Hi Gabi,

Here is the section from the FOD draft that includes the new PMIP-2 results. The radiative forcings have been modified based on new calculations. Note the PMIP-2 LGM model results included in the FOD do not include vegetation or atmospheric aerosol changes so for these results the radiative forcing estimate is 5.7 +/- 1.3 W/m<sup>2</sup>.

Subject: IMPORTANT - The next steps for chapter 6 enroute to THE FOD  
Date: Thu, 14 Jul 2005 21:48:56 -0600

<x-flowed>

Hi all - in the last few emails, we have suggested that you serve as "head" lead authors for the various sections of our chapter. One main purpose of this email is to make sure you are comfortable with the responsibility and have time for it. The other main goal is to explain what is expected of each of you.

First, here's a list of who's heading what sections. We picked you guys since you have proven to be intellectual leaders on the team, but also because you have track records of getting the job done on time. The one person we worry about is Olga, since she is leaving soon for the field, but nonetheless, we'd like all her input on Box 6.3 before she leaves. We will take over after then.

Exec Summary and Section 6.1 - PECK and EYSTEIN  
Section 6.2 - DAVID  
Section 6.3 - STEFAN  
Section 6.4 - BETTE  
Section 6.5 - KEITH  
Section 6.6 - FORTUNAT  
Box 6.1 - DAVID  
Box 6.2 - FORTUNAT  
Box 6.3 - OLGA  
Box 6.4 - KEITH

Second, what is needed? Here is a list that has come to mind. We'd like you all to comment on this list (use the email list used for this email), so that we all agree about what we're doing in the next couple weeks.

1) Your primary job is to make sure your section (text, tables, figs and refs) is as perfect as possible. Each of us has to be careful about how we schedule things so that we have the job DONE by July 24.

2) Each of you should solicit feedback and edits from the ENTIRE LA team, plus relevant CAs. This is obviously to get the best ideas possible, but also to ensure that all on the LA team have had input. Please create a check list and make sure that you have some sort of feedback (at least an "OK") from each LA. We suggest you start asap, and don't expect LAs to just respond to the emails we just sent - many of the LAs just don't respond in a timely fashion (thankfully, you guys are not on that list!).

2.5) Monitor all chapter listserv traffic for your input, as some LAs prefer to communicate only in that way.

3) Please explicitly ask for feedback on the text, tables, figs and refs.

4) With respect to text, try hard to get it down to size (see below), and to ensure that it is FOCUSED on only that science which is policy relevant. ALL TEXT should support an Exec Summary Bullet. If it doesn't the text should be removed, or a bullet created for discussion with our team. Also, although it is ultimately our job to try to make the chapter flow as one document, please do what you can to make your section's text flow with the other sections. Look to make sure all information is compatible across sections, and that the same type of language/style is used (to the extent you can).

4.4) We hope that you will start your process by reading THE ENTIRE CHAPTER carefully, and sending your comments for each section to the "head" LA for that section. This will get things moving fast, and help with the compatibility issues mentioned in #4 above.

5) With respect to the figures (and table), make sure each one is as compelling as possible. To save space (see below) you might decide a figure has to go. You might decide a new figure has to be included (only if there is space!). Work to get the figure redrafted where needed to be perfect - a sign of ultimate success will be that our figs get into the TS/SPM docs. Peck will be on that team, and will push hard, but figures MUST BE POLICY RELEVANT AND COMPELLING.

6) With respect to refs, please make sure that only the most relevant ones are cited, and that all of the citations are complete and entered into your copy of the master chapter endnote file. Although we expect to cite our own work where it makes sense, please be double sure that we're not going overboard in this regard - it won't look good to the outside world (e.g., skeptics) if we appear self-serving at all.

7) If you run into any debates that can't be easily solved (i.e. with all LAs happy), please consult with us. It is our job to make the ultimate calls, since someone has to do it. Again, it is our goal to make sure that no one is left with a bad feeling about our product. On the other hand, we have to make sure we stick to only the best science.

8) We'll be asking to make sure we have all the CAs listed. Let us know if you need to consult with any new ones. AGAIN, we must do what it takes to get the science and message as perfect as possible. CA consultation at this point is encouraged where it will help. For example, we need to get out the Pre-Q box to some Pre-Q experts - we are discussing w/ David.

9) At any point you need input, ask. We are happy to talk on the phone, and can call you or a group if you want a conference call. We are doing this already, and it can save lots of time. Or email. Both of us will be mostly around save a day or two.

10) Size and need to cut some sections. Because of recent changes in the TSU, we haven't been able to get the latest word, but we suspect

that our comments in the FOD draft just sent are true - some sections have a real space issue (factor in figures), others less so. We'll provide more on this soon, and we expect that if you follow the above guidelines, you'll be getting things into more focus, and hopefully less space - especially section 6.3. When thinking about Figs, Tables and Refs, also be thinking "How can I save space?"

11) Feel free to bring in other LAs to help you coordinate. For example, for section 6.3, Bette and Dominique (to be back soon) can be a big help, Stefan. Keith is working with Tim and Ricardo, but also some others to do the job he has left. Etc.

12) We will start sending more info next week, and will help reach consensus on what we're doing, and by when if needed. Let us know what we've missed, and what might be wrong or unclear.

Ok, that's more than enough.

Thanks again for helping us lead the next big push!

Best, Peck and Eystein

Subject: Re: paleoT  
Date: Fri Jul 15 11:06:31 2005

Tom,

This Briffa series is just a three site average (trees from Tornetrask, Polar Urals and Taimyr) - all in northern Eurasia. It is therefore for a limited region and is likely just the summer, whereas some of the others have regressed on annual T for the NH (or north of 20N).

Of these 3, the first two are in most of the other series (Esper, Crowley, Jones, Mann) and also for HF in Moberg. Not sure whether Taimyr is in any of the others. Esper uses a different standardization approach, but should have most of the same trees, but only TRW. The others use our reconstructions which have MXD is as well.

Have you tried these correlations after extracting the LF trends (say residuals from a 30 or 50 yr filter)? Would expect some of them to be much, much lower.

Keith's reconstruction that would be much better is the one that goes back to only about 1400. Do you have this? Go here [1]<http://www.ncdc.noaa.gov/paleo/paleo.html> then click on paleo data, then on obtaining and look for Keith's - it says 600 years in the title. You can get the data.

Cheers

Phil

At 21:57 14/07/2005, you wrote:

Phil,

I eventually refiltered all the paleo data and have compared these with likewise filtered MAGICC output. Very interesting results.

Can you comment, off the record, on Keith's paleo series.

Here are correlations of individual series against the 7 series average.

(Different series lengths, but essentially same results over common lengths.)

SERIES	1000-1610	1610-1995	1000-1995
Briffa	-.272	.262	.207
Esper	.583	.917	.687
Crowley	.879	.946	.902
Jones	.773	.917	.861
Mann	.760	.856	.822
M&J-NH	.929	.965	.936
Moberg	.904	.856	.871

Correlations with the climate model are not the same -- but Briffa is again the clear outlier.

Why?

Tom.

Hi,  
if what Tom writes is correct, then I would think it is not necessary to have a separate paper. But we need to be sure so as not to break any of the regulations since this will be one of the most scrutinized sections of the whole 4AR. I guess it is now up to how Keith and Tim takes the MWP box further and what ends up in the figure.

Cheers,  
Eystein

Subject: thoughts and Figure for MWP box  
Date: Mon Jul 18 17:12:06 2005

Dear Peck, Eystein and Tom

At this point we thought it was important to review where we think we are with the MWP Figure.

First, we have no objection to a Figure . Our only concerns have been that we should  
1/... be clear what we wish this Figure to illustrate (in the specific context of the MWP box) - note that this is very different from trying to produce a Figure in such a way as to bias what it says (I am not suggesting that we are, but we have to guard against any later charge that we did this). We say this because there are intonations in some of Peck's previous messages that he wishes to "nail" the MWP - i.e. this could be interpreted as trying to say there was no such thing, and

2/ ...agree that we have done this in the best way.

The truth is that there IS a period of relative warmth around the end of the 1st and start of the 2nd millennium C.E. , but that there are much fewer data to base this conclusion on (and hence the uncertainty around even our multiple calibrated multi-proxy reconstructions are wide). The geographical spread of data also impart a northern (and land) bias in our early proxy data. My understanding of Tom's rationale with the Figure is that we should show how, because the timing of maximum pre-20th century warmth is different in different records, the magnitude of the warmest period (for the Hemisphere , or globe, as a whole) is less than the recently observed warmth.

The reconstructions we plot in Chapter 6 already express the mean Hemispheric warmth (after various selection and scaling of data), and so the additional information that the MWP box figure should show must relate to the scatter of the proxy data. There seems to be a consensus that this is best done by showing individual records , and we are happy to agree. What we worry very much about, however, is that we should not produce a Figure that then conflicts with the picture of proxy evidence for Hemispheric mean warmth as a whole,shown in the main Chapter Figure. By showing a composite (as Tom has done) and scaling against another (30-90degrees N) temperature record - this is just what is done.

As we promised, Tim has produced a similar Figure, using the same series plus a few extras, but omitting the composite mean and the scaling against instrumental temperatures. The idea was to include as many of the original input series (to the various reconstructions) as we could - though avoiding conflicting use of different versions of the same data. The precise selection of records will have to be agreed and, presumably, based on some clear, objective criteria that we would need to justify (this will not be straight forward). This, along with Tom's plot (forwarded by Peck) is in the attachment.

We would like to get your opinion now, and especially Tom's, on the points regarding the composite and scaling. We would be in favour of just showing the series - but do they make the point (and emphasise the message of the text in the box)? Or does the scatter of the

various series as plotted, dilute the message about the strength of 20th century mean warming (note the apparently greater scatter in the 20th century in our figure than in Tom's)? Can you all chip in here please.

best wishes

Keith and Tim

P.S. We agreed in Beijing that we should definitely ask Tom to be a CA .

Tom et al  
thanks for remarks - in response to Tom's questions  
At 18:23 18/07/2005, Tom Crowley wrote:

a few comments -

1) are you trying to choose between my way of presenting things and your way - ie, w/out composite?

Yes

2) with your data, do they all go through from beginning to end?

pretty much - and have been standardised over the maximum period for each (not necessarily the best way?)

3) why include chesapeake, which is likely a salinity record?

Because Moberg used it in their latest reconstruction - I agree that I would not use it because of the dubious temperature signal (salinity effect and no local replication) and poor dating control (and I do not like the way the Moberg method effectively over weights the low-frequency predictor series in their analysis).

4) some of your data are from virtually the same site - Mangazeja and yamal are both w. siberia - I composited data available from multiple sites to produce one time series, which is equally counted against the other regions, which might (greenland, w.U.S., e. Asia) or might not have multiple records in them

Just to reiterate - I understood after the group chat with Susan S. in Beijing , that we were being asked to try to produce a "cloud" diagram including as many of "original" predictor series ,from all the reconstructions, to see if it provided an "obvious" picture of the unprecedented warming over the last millennium or so. Tim and I are in no way trying to produce a different Figure for the sake of producing a different Figure . In practice this is hard to do (because some records are sensible "local" composites already, and how far do you go in showing all input data? The problem of what and how to composite is tricky - and no obviously "correct" way is apparent. Having said this , Tom's way is fine with me (provided the composites are robust) and we get general agreement. Am happy to go with Tom's Figure , or version that incorporates as many records as possible - but as we have said - without the composite or temperature scaled add ons.

5) I am not sure whether it is wise to add me to the CA list, just because the reviewer

is supposed to be impartial and a CA loses that appearance of impartiality if he has now been included as a CA - may want to check with Susan S. on this one to be sure - still happy to provide advice

My own position on this is that you are an "unofficial" referee, who has (and still is) making a significant contribution - I see no conflict

6) I am happy to go in either direction - include or not include my figure - all I need are specific directions as to what to do, as CLAs you people need to decide, and then just tell me what or what not to do

Agree - CLAs please rule on the individual record/composite question - I am very happy to go with Tom's Figure. We did ours because we were asked to.

7) I am a little unhappy with the emphasis on hemispheric warmth - lets face it, almost all of the long records are from 30-90N - the question is: how representative is 30-90N to the rest of the world? for the 20th c. one can do correlations with the instrumental record, but co2 has almost certainly increased the correlation scale beyond what it was preanthropogenic.

Absolutely agree , and hope this comes over in text (and bullets) - if not needs strengthening (note David R's comments).

you could correlate with Quelcaya - not sure how many other records there are that are annual resolution - in the tropics I have produced a tropical composite (corals + Quelc.) but it only goes back to ~1780 - corals just don't live v long - in that interval at least the agreement is satisfactory with the mid latitude reconstruction but there is only 100 years extra of independent information beyond the instrumental record..

We have gone round in circles over this , but understand consensus to be that Quelc. not a clean temperature record. Agree corals would be better longer (the new coral-based reconstruction by Rob Wilson et al goes back to 1700 and shows unprecedented tropical warming . Along with the text from Julie we can not go much further, but the importance of extending the tropical (and SH records needs to be very clear)

.THIS MAY NEED TO BE ADDRESSED AS A GENERAL ISSUE SOMEWHERE (SHORTLY) IN YOUR DOC

Really hope it is already - but advise if you think not

tom

Thanks for this - lets take lead from J and E now (also can you advise on state of play with the Hegerl et al manuscript?)

thanks

Keith

Jonathan Overpeck wrote:

Hi Keith, Eystein and Tom: See below (**BOLD**) for my comments. Thanks for moving this forward and making sure we do it right (i.e., without any bias, or perception of bias).

Dear Peck, Eystein and Tom

At this point we thought it was important to review where we think we are with the MWP Figure.

First, we have no objection to a Figure . Our only concerns have been that we should 1/... be clear what we wish this Figure to illustrate (in the specific context of the MWP box) - note that this is very different from trying to produce a Figure in such a way as to bias what it says (I am not suggesting that we are, but we have to guard against any later charge that we did this). We say this because there are intonations in some of Peck's previous messages that he wishes to "nail" the MWP - i.e. this could be interpreted as trying to say there was no such thing, and

**SORRY TO SCARE YOU. I \*\*ABSOLUTELY\*\* AGREE THAT WE MUST AVOID ANY BIAS OR PERCEPTION OF BIAS. MY COMMENT ON "NAILING" WAS MADE TO MEAN THAT ININFORMED PEOPLE KEEPING COMING BACK TO THE MWP, AND DESCRIBING IT FOR WHAT I BELIEVE IT WASN'T. OUR JOB IS TO MAKE IT CLEAR WHAT IT WAS WITHIN THE LIMITS OF THE DATA. IF THE DATA ARE NOT CLEAR, THEN WE HAVE TO BE NOT CLEAR. THAT SAID, I THINK TOM'S FIGURE CAPTURED WHAT I HAVE SENSED IS THE MWP FOR A LONG TIME, AND BASED ON OTHER SOURCES OF INFO - INCLUDING KEITH'S PROSE. THE IDEA OF A FIGURE, IS THAT FIGURES CAN BE MORE COMPELLING AND CONNECT BETTER THAN TEXT. ALSO, THERE ARE MANY WAYS TO LOOK AT THE MWP, AND AS LONG AS WE DON'T INTRODUCE BIAS OR ANYTHING ELSE THAT WILL DILUTE THE MESSAGE IN THE END, THE IDEA IS TO SHOW THE MWP IN MORE WAYS THAN TWO (THAT IS, THE EXISTING FIGS IN THE TEXT THAT KEITH AND TIM MADE).**

2/ ...agree that we have done this in the best way.

The truth is that there IS a period of relative warmth around the end of the 1st and start of the 2nd millennium C.E. , but that there are much fewer data to base this conclusion on (and hence the uncertainty around even our multiple calibrated multi-proxy reconstructions are wide). The geographical spread of data also impart a northern (and land) bias in our early proxy data.

**NEED TO BE CLEAR ABOUT THIS BIAS IN THE CAPTION AND BOX TEXT**

My understanding of Tom's rationale with the Figure is that we should show how, because the timing of maximum pre-20th century warmth is different in different records, the magnitude of the warmest period (for the Hemisphere , or globe, as a whole) is less than the recently observed warmth.

**YES, BUT IN A WAY THAT SAYS "LOOK, HERE ARE THE ACTUAL REGIONAL CURVES - CHECK IT OUT FOR YOURSELF" INSTEAD OF JUST SAYING (IN A SCIENTIFICALLY MORE STANDARD MANNER - HERE ARE THE VARIOUS, MOST ROBUST, LARGE AREA RECONSTRUCTIONS. IN MY MIND, THE LATTER (KEITH/TIM FIGS IN THE MAIN TEXT) WILL BE THE MOST APPEALING/CONVINCING TO PALEOCLIMATE SCIENTISTS, BUT TOM'S MIGHT HELP THERE, AND CERTAINLY WITH NON-PALEO SCIENTISTS AND POLICY FOLKS. MIGHT HELP... IF IT DOESN'T NOTHING LOST, BUT IF IT COULD HURT CONVEYING UNDERSTANDING, THEN ITS BAD TO USE THE NEW FIGURE.**

The reconstructions we plot in Chapter 6 already express the mean Hemispheric warmth (after various selection and scaling of data), and so the additional information that the MWP box figure should show must relate to the scatter of the proxy data. There seems to be a consensus that this is best done by showing individual records , and we are happy to agree.

What we worry very much about, however, is that we should not produce a Figure that then conflicts with the picture of proxy evidence for Hemispheric mean warmth as a

whole, shown in the main Chapter Figure. By showing a composite (as Tom has done) and scaling against another (30-90degrees N) temperature record - this is just what is done.

ABSOLUTELY RIGHT - CAN'T HAVE CONFLICT.

As we promised, Tim has produced a similar Figure, using the same series plus a few extras, but omitting the composite mean and the scaling against instrumental temperatures. The idea was to include as many of the original input series (to the various reconstructions) as we could - though avoiding conflicting use of different versions of the same data. The precise selection of records will have to be agreed and, presumably, based on some clear, objective criteria that we would need to justify (this will not be straight forward). This, along with Tom's plot (forwarded by Peck) is in the attachment.

We would like to get your opinion now, and especially Tom's, on the points regarding the composite and scaling. We would be in favour of just showing the series - but do they make the point (and emphasise the message of the text in the box)? Or does the scatter of the various series as plotted, dilute the message about the strength of 20th century mean warming (note the apparently greater scatter in the 20th century in our figure than in Tom's)? Can you all chip in here please.

best wishes

WHAT ABOUT THE IDEA THAT WE ONLY SHOW THE SERIES FOR THE MWP, SINCE THE COMPARISON TO THE 20TH CENTURY IS DONE WELL (AND BEST?) IN THE TEXT FIGS (WHICH I'M ATTACHING JUST IN CASE TOM DOESN'T HAVE, ALONG WITH THE TEXT - IF YOU HAVE TIME, TOM, PLEASE READ COMMENT ON ANYTHING YOU WISH, BUT CERTAINLY THE LAST 2000 YEARS BIT - ASSUME YOU'LL BE DOING THIS AT THE REVIEW STAGE ANYHOW...)

ANOTHER THING THAT IS A REAL ISSUE IS SHOWING SOME OF THE TREE-RING DATA FOR THE PERIOD AFTER 1950. BASED ON THE LITERATURE, WE KNOW THESE ARE BIASED - RIGHT? SO SHOULD WE SAY THAT'S THE REASON THEY ARE NOT SHOWN? OF COURSE, IF WE ONLY PLOT THE FIG FROM CA 800 TO 1400 AD, IT WOULD DO WHAT WE WANT, FOCUS ON THE MWP ONLY - THE TOPIC OF THE BOX - AND SHOW THAT THERE WERE NOT ANY PERIODS WHEN ALL THE RECORDS ALL SHOWED WARMTH - I.E., OF THE KIND WE'RE EXPERIENCING NOW.

TWO CENTS WORTH

Keith and Tim

P.S. We agreed in Beijing that we should definitely ask Tom to be a CA .

TRUE - BUT HAS ANYONE CONFIRMED W/ TOM. TOM, YOU OK W/ THIS?

THANKS - A GREAT DISCUSSION, AND LETS SAY THE JURY IS STILL OUT ON THIS FIGURE UNTIL WE ALL ARE COMFORTABLE WITH WHAT IT LOOKS LIKE IN THE END.

BEST, PECK

Dear Keith and Ed,

Please, find attached the new version of the SH figure for the IPCC. I have now included the New Zealand record. All the records have been scaled to 4 °C amplitude. Variability in the Tas record is reduced compared to New Zealand and Patagonian records. The reference lines is the mean used for the calibration period in each record, 15 C for New Zealand, 14.95 C for Tasmania and 0 C for the Patagonian records (they show departures). Please, let me know if you want to introduce some changes in the figure. The opposite phase in the Patagonia-New Zealand records is so clear before 1850, which is consistent with our previous TPI. For instance, in the instrumental record the 1971 and 1976 are the coolest summer in northern Patagonian during the past 70 years, but the warmest in New Zealand reconstruction!! This out of phase relationship between regions in the Southern Hemisphere points out to the difficulty of using few records to get a hemispheric average. Cheers,

Ricardo

Thanks Ed - Ricardo, can you get the data from Henry? What do you think, Keith?

Best, Peck

Dear Stefan,

The distinction here is that GCMs attempt to calculate from first principles the zeroth and first order processes that dominate the problem they are studying, whereas EMICs parameterize many of those processes. The fact that EMICs can reproduce GCM results suggest that their parameterizations have been tuned to do so - but this does not in any way imply that if one alters the forcing or boundary conditions outside of a small range, or apply them to completely different problems, that the two types of models will react similarly. In fact, there is a history of this - the first "EMICs" had a very large sensitivity to a 2% solar insolation change; then they had to be re-tuned to prevent that from happening. EMICs are used for paleo-problems because of their ability to take large time-steps, but there is no free lunch - in doing so, they sacrifice calculating the fundamental physical processes the way the real world does it. GCMs have storms, they have real water vapor transports, they have winds calculated from solving the conservation of momentum equation, etc. etc. There is a quantum difference between the fundamental approaches - it is not a continuum, in which there are no real differences, everything is simply a matter of opinion, there is no such thing as truth - that's the argument that greenhouse skeptics use to try to make science go away.

Because we can't use GCMs for long-time scale problems, we do the best we can - we use these heavily parameterized models. If we could use GCMs for those problems, EMICs could then be tuned to produce the GCM results on those time-scales as well. But in this case we have no way to validate the EMIC results - and since the first principles are not being used, we cannot know whether they represent a physically consistent solution or not. Therefore all they can do is suggest interactions among processes, a useful though not definitive addition to the field.

David

ps - concerning CLIMBER-2, I asked a number of leading climate scientists to read the model description paper. Peter Stone was the only person I asked who thought the model was at all useful for studying the types of problems we are discussing. And it was not only GCM scientists. If you want to hear further cogent arguments concerning its inapplicability, consider contacting Bill Rossow (the recent winner of a major honor as a leading climate scientist) but make sure your email program or telephone accepts unexpurgated text.

Hi all

think this is resolved now (virtually) -

We use series that total to Tom/Gabi composite, and we can cite this as an example of the scatter of regional records "in a typical reconstruction". This avoids very difficult issue of what is the best way to aggregate certain data sets - we are simply illustrating the point with one published (by then) data set.

The issue of the composite is then not an issue either, because it is not a new (unpublished) composite that we were concerned about - though I still believe it is a distraction to put the composite in. It would be best to use data from 800 or 850 at least, and go to 1500 (?) and presumably normalise over the whole period of data shown. OK? Even though you guys all wish to go with the reduced period (ie not up the present), but my own instinct is that this might later come back to haunt us - but will take your lead.

I agree the look of the Figure should match the others.

So, if Tom will send the data sets (his regional curves), Tim will plot and send back asap for scrutiny. Thanks Tom and thanks for your help with this - further comments on latest version of 6.5 (last 2000 years) still welcome, though will be incorporating a few changes in response to David and Fortunat input, and SH bit (from Ricardo and Ed) still to go in and regional section to be revised (after input from Peck et al.)

cheers

Keith

.

At 21:42 19/07/2005, Jonathan Overpeck wrote:

Hi Keith and Tim: Just got off the phone with Eystein, and hopefully he will sleep ok knowing that we have a plan for the MWP fig and Tom...

Please ask questions if we don't cover all the key points, but here's what we think:

- 1) the MWP fig should span the MWP only, and should emphasize variation in regional amplitude (we agree that we must be clear that this fig is not a reconstruction) - that is, it is best to use time series representing regions, assuming that the regional series do represent a region ok with one or more input series. We want to avoid a regional bias if we can - this is what got us into all the MWP misunderstanding in the first place, perhaps (e.g., nice MWP in Europe/Atlantic region - must be global)
- 2) If you guys could agree on the series and the interval, that'd be great. We agree it would be good to start before 1000 and end before the Renaissance (15th century?). If you want more feedback on these issues, we're happy to provide, but it seems logical

that you pick series and intervals so that each series covers the entire interval selected.

3) Don't use the Chesapeak record - it is likely biased by salinity

4) We'd like Keith and Tim to draft the final figure so that it matches the look and style of the other two figs they have made. Hope this is doable. Tom, does Keith have all the data? Thanks for sending if not.

5) We agree that Tom should NOT be a CA given that he was officially one of the ZOD reviewers. Of course, this doesn't represent a real conflict, but we need to avoid even the appearance of conflict. We greatly appreciate all the feedback that Tom is providing! Is this plan ok w/ you Tom? We think you're cool with it, but just want to check one more time.

That... it is. Please let us know if there are any more questions. Keith - feel free to try and get Eystein on his cell doing your work hours if you want quick feedback. Or we can do this by email - he's not in a very email friendly place right now, but the fishing appears to be ok.

Again, thanks to you both for all the discussion and thought that has gone into this figure.

Best, peck

Dear chapter 6 friends,

I have a request on procedure. In the interest of a good and constructive working atmosphere, I would suggest that all of us focus on sober scientific arguments and refrain from unnecessarily derogatory comments about the work of colleagues. I'm referring in this case to David's comment

- this reference is overused, especially for such a simplistic model

The reference concerned is our theory of DO events which appeared in Nature in 2001 and has since been cited 133 times according to the Web of Science (a sign of overuse?) The model concerned is the CLIMBER-2 model, featured in over 50 peer-reviewed publications since 1998, including 7 in Nature and Science.

This model is different from David's model, because it has been constructed for a different purpose, but it is not "simplistic". It would never occur to me to call David's model "simplistic" because it does not include an interactive continental ice sheet model, vegetation model, carbon cycle model, sediment model and isotope model.

I'm absolutely open to any rational scientific criticism and discussion, but I can see no purpose in derogatory statements like the above, which include not even a trace of scientific argument. This kind of thing only poisons the working atmosphere in our group, which I thought was very positive and a great pleasure in Beijing.

Regards, Stefan

Hi Tom,

as a followup to Keith's email, it might be quite likely that one of the series you plot is replaced by the instrumental record after 1960, because the file from Crowley and Lowery that is available at the WDC-Paleoclimate contains such a record. The header states:

-----  
Crowley and Lowery 2000 (Ambio 29, 51)  
Northern Hemisphere Temperature Reconstruction  
Modified as published in Crowley 2000  
(Science v289 p.270, 14 July 2000)  
Data from Fig. 1, Crowley 2000:  
Decadally smoothed time series of Crowley-Lowery reconstruction  
spliced into smoothed Jones et al instrumental record after 1860  
(labeled CL2.Jns11), and a slight modification (labeled CL2)  
of the original Crowley and Lowery reconstruction to 1965.

-----  
The URL of this file is:

[1][ftp://ftp.ncdc.noaa.gov/pub/data/paleo/gcmoutput/crowley2000/crowley\\_lowery2000\\_nht.txt](ftp://ftp.ncdc.noaa.gov/pub/data/paleo/gcmoutput/crowley2000/crowley_lowery2000_nht.txt)  
and it is listed here:

[2]<http://www.ncdc.noaa.gov/paleo/recons.html>

Cheers

Tim

At 12:22 18/07/2005, Keith Briffa wrote:

as a first quick response - the Crowley numbers came from his paper with Lowery. I seem to remember that there were 2 versions of the composite that he produced - certainly we used the data that did not include Sargasso and Michigan site data. I presume the other (from the CRU web site) were the data used by Phil and Mike Mann that they got from him (where exactly did you pick them up from?) and could be the other data set (with those sites included). It seems odd that the values are so high in the recent period of this series and could conceivably be instrumental data, but would have to check. The scaling of the data we used to produce the Crowley curve that formed one of the lines in our spaghetti diagram (that we put on the web site under my name and made available to NGDC), was based on taking the unscaled composite he sent and re-calibrating against April - Sept. average for land North of 20 degrees Lat., and repeating his somewhat bazaar calibration procedure (which deliberately omitted the data between 1900-1920 that did not fit with the instrumental data (remember his data are also decadal smoothed

values). In fact , as we were using summer data we calibrated over 1881-1900 (avoiding the high early decades that I still believe are biased in summer) and 1920 - 1960 , whereas he used 1856-1880 and 1920-1965. Of the precise details might differ - but the crux of the matter is that I suspect one of the Figures you show may have instrumental data in the recent period - but not ours. If you say exactly where these series came from I can ask Tim (who will have done the calibrations) to check.

As for the second question , the QR data are averaged ring widths from relatively few site chronologies in the high north (mostly N.Eurasia - Scandinavia, Yamal, Taimyr), though with a few other site data added in as stated. The 2001 data are the MXD data from near 400 sites and provide the best interannual to multidecadal indication of summer temps for land areas north of 20 degrees than any of the true proxy (ie not including instrumental ) data. No idea what the correlation over the common 600 year period is - but I have never said that the ring width is anything other than summer temps for the area it covers .

Keith

At 20:38 15/07/2005, you wrote:

Keith,

Look at the attached. Can you explain to me why these plots differ -- particularly after 1880?

Could you also explain why the Briffa data in QR 2000 are so poorly correlated with the Briffa 2001 data?

I think I know the answers, but I want an independent and spontaneous answer from you.

Thanks,

Tom.

Hi Ricardo and all

this all seems fine with me - the question of the temperature observations is a moot one - but some included seems a good idea - 1 South American and 1 New Zealand is fine - length not as important as proximity to the records shown (but need to see what they look like). will wait on other numbers - Henry is best qualified to cite most appropriate SH borehole data and could supply a line of text . Ricardo can you ask him for these?

best wishes

Keith

At 13:52 20/07/2005, Ricardo Villalba wrote:

Hi Keith, Ed, Peck, Eystein

Regarding Peck's suggestions,

- 1) should we include instrumental data? If not, it could lessen the impact. Rio de Janeiro, starting in 1851, is the longest, homogeneous temperature record from the Southern Hemisphere. In New Zealand and Australia, temperature records start at the same time. We do not have any long record for the 18th century, even the first half of the 19th century. The hemispheric record from the Southern Hemisphere will be discussed in Chapter 2 and we do not have any additional information to provide.
- 2) we need to include the two borehole (see previous email from me and Ed) Definitely!! I do not have the records here in Mendoza. Keith, do you have access to these data? As soon as I receive the borehole records I will incorporate them in the figures. I would appreciate receiving the key references to properly cite the records.
- 3) we would like to ask Keith and Tim (pretty please...) to draft the final figure so that it matches the other in the section and MWP box. Is this ok, and do you have the data to do the job. If not, we trust your kind colleagues can send upon request?

At the time the figure is ready, I will send all the data to Keith and Tim to draft the final figure, and the final text to incorporate in the FOD.

Cheers,

Ricardo

Keith, if you can find more I see no problem - it seems that a lot of the data you used was via Cook and colleagues - I was unable to locate a full length record from Quebec in that time series, but maybe you are relying on something else - if so can I have it!?

other suggestions: provide a more general label to sites - eg, mangazeyek (sp)/yamal could be listed as polar urals - taimyr central Siberia.

China should be relabeled as east Asia as it does include some information from Japan and the Tibetan Plateau (L. Thompson) and we don't want to get into some political to-do by calling Tibet "Chinese".

that's all I can think of for present, good sailing, tom

Keith Briffa wrote:

Hi all

think this is resolved now (virtually) -

We use series that total to Tom/Gabi composite, and we can cite this as an example of the scatter of regional records "in a typical reconstruction". This avoids very difficult issue of what is the best way to aggregate certain data sets - we are simply illustrating the point with one published (by then) data set.

The issue of the composite is then not an issue either, because it is not a new (unpublished) composite that we were concerned about - though I still believe it is a distraction to put the composite in. It would be best to use data from 800 or 850 at least, and go to 1500 (?) and presumably normalise over the whole period of data shown. OK? Even though you guys all wish to go with the reduced period (ie not up the present), but my own instinct is that this might later come back to haunt us - but will take your lead.

I agree the look of the Figure should match the others.

So, if Tom will send the data sets (his regional curves) , Tim will plot and send back asap for scrutiny. Thanks Tom and thanks for your help with this - further comments on latest version of 6.5 (last 2000 years) still welcome , though will be incorporating a few changes in response to David and Fortunat input , and SH bit (from Ricardo and Ed) still to go in and regional section to be revised (after input from Peck et al.)

cheers

Keith

.  
At 21:42 19/07/2005, Jonathan Overpeck wrote:

Hi Keith and Tim: Just got off the phone with Eystein, and hopefully he will sleep ok knowing that we have a plan for the MWP fig and Tom...

Please ask questions if we don't cover all the key points, but here's what we think:

1) the MWP fig should span the MWP only, and should emphasize variation in regional amplitude (we agree that we must be clear that this fig is not a reconstruction) - that is, it is best to use time series representing regions, assuming that the regional series do represent a region ok with one or more input series. We want to avoid a regional bias if we can - this is what got us into all the MWP misunderstanding in the first place, perhaps (e.g., nice MWP in Europe/Atlantic region - must be global)

2) If you guys could agree on the series and the interval, that'd be great. We agree it would be good to start before 1000 and end before the Renaissance (15th century?). If you want more feedback on these issues, we're happy to provide, but it seems logical that you pick series and intervals so that each series covers the entire interval selected.

3) Don't use the Chesapeake record - it is likely biased by salinity

4) We'd like Keith and Tim to draft the final figure so that it matches the look and style of the other two figs they have made. Hope this is doable. Tom, does Keith have all the data? Thanks for sending if not.

5) We agree that Tom should NOT be a CA given that he was officially one of the ZOD reviewers. Of course, this doesn't represent a real conflict, but we need to avoid even the appearance of conflict. We greatly appreciate all the feedback that Tom is providing! Is this plan ok w/ you Tom? We think you're cool with it, but just want to check one more time.

That... it is. Please let us know if there are any more questions. Keith - feel free to try and get Eystein on his cell doing your work hours if you want quick feedback. Or we can do this by email - he's not in a very email friendly place right now, but the fishing appears to be ok.

Again, thanks to you both for all the discussion and thought that has gone into this figure.

Best, peck

<x-flowed>

Tim, we are getting close but there are a few items to discuss:

- 1) seven of the eight time series are from the Hegerl et al paper, now out for review in Nature
- 2) the eighth time series is from Brian Luckmans recent extension of the Alberta record to the 10th century - we used his original time series in the H et al paper because the comparisons between model and observations had been going on for a while, in fact before the new Luckman paper came out, and we did not want to switch horses in midstream by changing the composite - as you know the Luckman paper is either accepted or published in CD, so there is no problem changing that
- 3) although technically the time series are not the same they are very close, if you want me to do some comparisons I can, but I could not get to it until probably tuesday of next week - I don't particularly see any problem in making such an addition
- 4) we cannot extend the time series back to 800 without dropping out something - the reason we start at 945 is that is the first year when all the records are available - if we go back to 800 we do so at the cost of dropping 2 or possibly even 3 records. as our Dark Ages reconstruction starting at 560 indicates (att.), the biggest warming between 800-1900 is in the late 10th century (960-995), we did not think we missing out on anything by starting at 945 rather than 800.

I await your feedback on this increasingly intricate issue, tom

Ricardo

Tim is contacting Henry now - so forget Boreholes for time being  
cheers

Keith

At 15:23 21/07/2005, Ricardo Villalba wrote:

Hi Keith and all,

Following Peck's advise I will include for each reconstruction the observed record. Obviously, I have the Patagonian instrumental records, but I need from Ed the Tasmania and Hokitika (New Zealand) observed records. Sorry for my ignorance on borehole, but I am not familiar with Henry's work. If you send me his e-mail, I could ask him for the data and a line of text on borehole from the SH. Cheers,

Ricardo

Hi Ricardo and all

this all seems fine with me - the question of the temperature observations is a moot one - but some included seems a good idea - 1 South American and 1 New Zealand is fine - length not as important as proximity to the records shown (but need to see what they look like).

will wait on other numbers - Henry is best qualified to cite most appropriate SH borehole data and could supply a line of text . Ricardo can you ask him for these?

best wishes

Keith

<x-flowed>

Hi Tom,

In Keith's email below, when he says "we use series that total to Tom/Gabi composite", he doesn't mean that *\*our\** mock up of the figure uses these series, but that if the series shown in *\*your\** draft figure are the same as those used in the Hegerl/Crowley recon that is currently submitted ("...a twice validated climate record...") then we will go with *\*your\** figure. It is fine then to include the "composite series" and the instrumental data and a temperature scale. Our previous concerns about these latter points were that it might be seen as another new NH temperature reconstruction. But if in fact the composite and its expression as a temperature are not a new NH T recon, but are in fact identical to the published (submitted, at least) Hegerl/Crowley NH T recon (which is already included in the main intercomparison figure) then there's no problem.

Does your figure equate to the new Hegerl/Crowley NH T recon? If so, we should go with your MWP figure, though the CLAs want me to draw it in the same style as the others and also cut the time period down to a few centuries spanning the MWP. Keith suggests beginning in 800 or 850.

Would it be possible therefore to send the data series you used for your figure, but beginning in 800/850, so I can plot the figure in the required form?

Cheers

Tim

Hi Eystein,

Thanks for your comments. With respect to the suggested changes in paragraphs 1,2 and 4, they seem fine to me. However, I think we need to include in paragraph 5 potential reasons as to why the substantial (and not just significant) high latitude warming that appears in the mid-Pliocene record is not produced in GCMs in response to higher CO<sub>2</sub>, in general - otherwise we leave the reader with a big question and no possible solution. The tendency of GCM simulations for the future climate to produce an NADW decrease forces those simulations to have minimal high latitude warming in the North Atlantic, exactly opposite the inference from the Pliocene paleo-record (which is quite robust in this respect at least). If the Pliocene record is indicating the opposite of what current models are predicting, it may be offering us a valuable clue...

The suggested reasons also include the comment that the lack of land ice at high northern latitudes might be a strong contributing cause - which would make it a no-analog situation, and hence not fully a GCM problem.

I would favor leaving those two sentences as they were.

David

Hi David,  
thanks for the reply. I think your arguments to add some comments of explanation re Pliocene warmth are convincing and that there is potential relevance for IPCC concerning lat. heat transport in a world with less land and sea ice. My concern is that I don't think the text should be interpreted to imply that the Mid Pliocene was free of Arctic sea ice and Greenland was ice free. There is evidence from the recent IODP Central Arctic Drilling (have to check what ref. to use) of sea ice cover through the Pliocene. I have published on IRD evidence for a Greenland ice sheet of some sort. Concerning THC, N Atlantic data indicate strong presence of NADW akin to now, but we cannot constrain overturning rate. Both Nordic Seas and Arctic Ocean was poorly ventilated and deep water formation to feed overflows was shallower, perhaps due to higher temperature?

Instead of deleting the section I proposed, I suggest changing it as follows: After (Rind and Chadler 1991) add , "for which available proxy data are inconclusive", and

Instead of writing "absence of land ice", write " reduced extent of land and sea ice". I will find the best refs for this on Monday.

Cheers  
Eystein

Hi all, there is another reason why I should not be formally listed as an LA - it is my understanding that IPCC contributors have to be a little careful about getting involved in political matters that could be used to impugn the integrity of the process - well I am starting to do just that, with the attached commen in Eos, plus some radio interviews where I have been somewhat pointed in my thoughts.

I suppose its still ok to be a reviewer, but even then you might keep these comments in mind, tom

Subject: Last Millennium section 6.5 - comments by SR

Date: Tue, 26 Jul 2005 12:09:33 +0200

Cc: wg1-ar4-ch06@joss.ucar.edu, Jonathan Overpeck <jto@u.arizona.edu>, Eystein Jansen <Eystein.Jansen@geo.uib.no>

Hi Keith and all, (please everyone have a look at point (4))

I think section 6.5 is in remarkably good shape (certainly compared to my own..).

There are some comments from me:

(1) About the new proxy reconstructions, the section says: "Most of these are shown..." in the Figure. This immediately raises the question: why not all? Which one is not shown? This section will be scrutinised with great suspicion by some people, so we need to be careful.

Can you clarify which one you left out, and why? Or can we just write: "These are shown..." That would be much nicer.

(2) Several times you say "simply scaled" - would "scaled" do as well? The "simply" in this context sounds a bit like we criticise that.

(3) Is "predictand" a word that everybody knows? I'd never seen it before.

(4) Now here is my biggest question, that I think we need to discuss in the whole group. Figure 6.5.2-1 shows simulations of the past millennium, relative to 1500-1899 means. Is this really the best reference period?

Contra: it differs from how we show the data reconstructions, i.e., relative to 1961-1990. Everyone knows what that climate actually was, since there are good instrumental data for 1961-1990, so that it makes sense to look at changes relative to that period. Nobody knows what the real 1500-1899 mean was, so this is a fictitious baseline.

Pro: it gets rid of "end effects", i.e. model initialisation problems at the beginning (as in Von Storch 04), and different anthropogenic forcings used at the end (e.g. some ignore aerosols); the simulations look closer together in this way (right?)

I have not formed a clear opinion on what is best.

(5) Also on the figures: I like the grey bands, but here's a suggestion for improvement: instead of leaving the core region between those two bands white, I think they should also be shaded - either the same grey, or a darker shade of grey. This makes it more clear that we are talking about one, wide uncertainty band here, not about two separate things. It had me confused at first when I saw it, even though I was there when we discussed this in Beijing.

Final point: we need to keep an eye on developments concerning the model tests of the proxy method, there seem to be several important things in the pipeline there.

Cheers, Stefan

Subject: MWP figure  
Date: Tue, 26 Jul 2005 20:00:29 +0100  
Cc: t.osborn@uea.ac.uk

Dear Keith, Peck and Eystein,

as you'll have seen from Tom C's replies to my fairly direct requests for the data that went into his MWP figure, he seems somehow reluctant to send it to me and prefers me to find it myself (including spending a week re-assembling a Mongolian composite). I have no time to do this, so have instead reverted to using the very similar data that we already had. I'm sure it's so similar that it tells the same story.

So, the attached file is my latest attempt at the MWP figure. It shows 8 local/regional proxy series, normalised over a common period after filtering to the 20-year and longer time scale. It also shows a composite mean, and no temperature scale. The period covered is 850 to 1350.

What do you think? Hopefully it is what you want.

I've started on the SH figure, having received data from Ricardo and borehole series for SH, S. Africa and Australia from Jason/Henry. I need to sort out Tasmania / New Zealand instrumental data - Ed has this, though I could extract appropriate boxes from the Jone et al. gridded data set if necessary.

I'll include these series:

S American trees\*2 plus instrumental T overlaid

S African and Australian boreholes (must also overlay instrumental T to explain why values are all negative - due to early sampling prior to strongest warmng)

Tasmanian and New Zealand trees\*2 plus instrumental T)

It may be Friday by the time I get this one done.

Cheers

Tim

Subject: Re: New versions  
Date: Thu Jul 28 09:37:18 2005  
Cc: Susan Solomon <ssolomon@al.noaa.gov>

Kevin/Susan,

I'll look over 3.9. A quick look at the back references to sections which contain the detail summarized here, suggests that you've got the right level of section. I guess we could add a sentence to say that this/these are the principal section(s), but the whole of the x.x section is likely also relevant.

I've added Susan in to show what we're doing. It might be appropriate for other chapters. Part of my reason was traceability, but also we are referring to subsequent sections in Chapters 4 and 5.

The figures seem to be coming along well. Pdfs are also. I'll send another reminder about these out later today, when I've had one last look for a few of them. I'll attach section numbers as there are so few now.

Cheers

Phil

The bulleted points and back references are below.

- Global-mean surface temperatures show overall warming of 0.75°C over the 1901-2004 period although rates of temperature rise are much greater after 1979. Both land surface air temperatures and SST show warming although land regions have warmed at a faster rate than the oceans for both hemispheres in the past few decades, consistent with the much greater mass and thermal inertia of the oceans. Some areas have not warmed in recent decades, and a few have cooled although not significantly. [3.2.2]
- The warming of the climate is consistent with a widespread reduction in the number of frost days in mid-latitude regions. The latter is due to an earlier last day of frost in spring rather than a later start to the frost season in autumn. The increase in the number of daily warm extremes and reduction in cold extremes across over 70% of land regions studied have been most marked at night over the 1951-2003 period. The greater increase in nighttime as opposed to daytime temperatures has continued. [3.8.2.1]
- Widespread (but not ubiquitous) decreases in continental DTR since the 1950s occur with increases in cloud amounts, as expected from the impact of cloud cover on solar heating of the surface. [3.2.2; 3.4.3]
- The temperature increases are consistent with the observed nearly worldwide reduction in mountain glacier mass and extent. A few regions of the world where mountain glacier termini are determined by winter precipitation totals, as opposed to summer temperatures, do show some advances, but these are consistent with changes in circulation and associated increases in winter precipitation (e.g., southwestern Norway, parts of coastal Alaska, southern Chile and Fjordland of the South Island of New Zealand). Tropical ice caps in South America, Africa and Tibet have all shown remarkable declines in recent

decades. If continued, some may disappear within the next 30 years. Reduction in mass of such glaciers depends on local heat budgets, which is not necessarily reflected in local temperature changes. The temperature records all show a slight warming, but nowhere near the magnitude required to explain the rapid demise of the many of the ice caps. [4.5]

- Snow cover has decreased in many NH regions, particularly in the spring season, consistent with greater increases in spring as opposed to autumn temperatures in mid-latitude regions. The decrease is accompanied by increased active layer thickness above permafrost and decreased seasonally frozen ground depths. [3.3.2.3; 4.2.4, 4.8]

- Sea-ice extents have decreased in the Arctic, particularly in the spring and summer seasons, and patterns of the changes are consistent with regions showing a temperature increase, although changes in winds are also a major factor. Decreases are found in the length of the freeze season of river and lake ice. [3.2.2.3; 4.3, 4.4, 5.3.3]

- Surface temperature variability and trends since 1979 are consistent with those estimated by most analyses of satellite retrievals of lower-tropospheric temperatures, provided the latter are adequately adjusted for all issues of satellite drift, orbit decay, different satellites and stratospheric influence on the T2 records, and also with ERA-40 estimates of lower-tropospheric temperatures. The range from different datasets of global surface warming since 1979 is 0.15 to 0.18 compared to 0.12 to 0.19 K decade<sup>-1</sup> for MSU estimates of lower tropospheric temperatures. [3.4.1]

- Stratospheric temperature estimates from radiosondes, satellites (T4) and reanalyses are in qualitative agreement recording a cooling of between 0.3 and 0.8°C decade<sup>-1</sup> since 1979. Increasing evidence suggests increasing warming with altitude from 1979 to 2004 from the surface through much of the troposphere in the tropics, cooling in the stratosphere, and a higher tropopause, consistent with expectations from observed increased greenhouse gases and changes in stratospheric ozone. Over extratropical land, the larger warming at night is associated with larger surface temperature changes. [3.4.1]

- Radiation changes at the top-of the atmosphere from the 1980s to 1990s, possibly ENSO related in part, appear to be associated with reductions in tropical cloud cover, and are linked to changes in the energy budget at the surface and in observed ocean heat content in a consistent way. [3.4.3; 3.4.4]

- Surface specific humidity has also generally increased after 1976 in close association with higher temperatures over both land and ocean. Consistent with a warmer climate, total column water vapour has increased over the global oceans by  $1.2 \pm 0.3\%$  from 1988 to 2004, consistent in patterns and amount with changes in SST and a fairly constant relative humidity. Upper tropospheric water vapour has also increased in ways such that relative humidity remains about constant, providing a major positive feedback to radiative forcing. [3.4.2]

- Over land a strong negative correlation is observed between precipitation and surface temperature in summer and in low latitudes throughout the year, and areas that have become wetter, such as the eastern United States, have not warmed as much as other land areas. Increased precipitation is associated with increases in cloud and surface wetness, and thus increased evaporation. Although records are sparse, continental-scale estimates of pan evaporation show decreases, due to decreases in surface radiation associated with

increases in clouds, changes in cloud properties, and increases in air pollution in different regions from 1970 to 1990. There is tentative evidence to suggest that this has reversed in recent years. The inferred enhanced evaporation and reduced temperature increase is physically consistent with enhanced latent versus sensible heat fluxes from the surface in wetter conditions. [3.3.5; 3.4.4.2]

- Surface observations of cloud cover changes over land exhibit coherent variations on interannual to decadal time scales which are positively correlated with gauge-based precipitation measurements. [3.4.3]

- Consistent with rising amounts of water vapour in the atmosphere, increases in the numbers of heavy precipitation events (e.g., 90/95<sup>th</sup> percentile) have been reported from many land regions, even those where there has been a reduction in total precipitation. Increases have also been reported for rarer precipitation events (1 in 50 year return period), but only a few regions have sufficient data to assess such trends reliably. [3.4.2; 3.8.2.2]

- Patterns of precipitation change are much more spatially- and seasonally-variable than temperature change, but where significant changes do occur they are consistent with measured changes in streamflow. [3.3.4]

- Droughts have increased in various parts of the world. The regions where they have occurred seem to be determined largely by changes in SSTs, especially in the tropics, through changes in the atmospheric circulation and precipitation. Inferred enhanced evaporation and drying associated with warming and decreased precipitation are important factors in increases in drought. In the western United States, diminishing snow pack and subsequent summer soil moisture reductions have also been a factor. In Australia and Europe, direct links to warming have been inferred through the extreme nature of high temperatures and heat waves accompanying drought. [3.3.4, QACCS 3.3, 3.8.3, 4.x.x]

- Changes in the freshwater balance of the Atlantic Ocean over the past four decades have been pronounced as freshening has occurred in the North Atlantic and also south of 25°S, while salinity has increased in the tropics and subtropics, especially in the upper 500 m. The implication is that there have been increases in moisture transport by the atmosphere from the subtropics to higher latitudes, in association with changes in atmospheric circulation, including the NAO, thereby increasing precipitation over the northern ocean and in adjacent land areas (as observed). [3.3.2, 3.3.3, 5.3.2, 5.5.3]

- Changes in the large-scale atmospheric circulation are apparent. Increasing westerlies have been present in both hemispheres as enhanced annular modes. In the NH, the NAM and NAO change the flow from oceans to continents and are a major part of the wintertime observed change in storm tracks, precipitation and temperature patterns, especially over Europe and North Africa. In the SH, SAM changes, in association with the ozone hole, have been identified with recent contrasting trends of large warming in the Antarctic Peninsula, and cooling over interior Antarctica. [3.5, 3.6, 3.8.3]

- The 1976/1977 climate shift toward more El Niños has affected Pacific rim countries and monsoons throughout the tropics. Over North America, ENSO and PNA-related changes appear to have led to contrasting changes across the continent, as the west has warmed more than the east, while the latter has become cloudier and wetter. [3.6, 3.7]

- Variations in extratropical storminess are strongly associated mostly with changes in mean atmospheric circulation, such as changes and variations in ENSO, NAO, PDO, and SAM. Wind and significant wave height analysis support the reanalysis-based evidence for an increase in extratropical storm activity in the NH in recent decades. After the late 1990s, however, some of these variations seemed to change sign. [3.5, 3.6, 3.8.3.2]
- Changes are observed to occur in the number, distribution and tracks of tropical storms that are clearly related to ENSO phases and to a slightly lesser extent to the AMO and QBO modulations. Increases in intensity and lifetimes of tropical storms since the 1970s are consistent with increases in SSTs and atmospheric water vapour. [3.8.3.1]
- Sea level likely rose about  $18 \pm 3$  cm during the 20<sup>th</sup> century, but increased  $3.0 \pm 0.4$  mm/year after 1992, when confidence increases from global altimetry measurements. During this period, glacier melt has increased ocean mass by order 1.0 mm/year, increases in ocean heat content and associated ocean expansion are estimated to contribute 1.6 mm/year, while changes in land water storage are uncertain but may have taken water out of the ocean. Isostatic rebound contributes about 0.3 mm/year. This near balance gives increased confidence that the observed sea level rise is a strong indicator of warming, and an integrator of the cumulative energy imbalance at the top of atmosphere. [4.5, 4.7, 4.9.8, 5.2, 5.5]

At 23:47 27/07/2005, Kevin Trenberth wrote:

Phil

I placed new versions of the figure and text files on my ftp site. I implemented your suggestion of adding section numbers to the 3.9. I used the ones from the ZOD wrt other chapters. So they may change. I also added a small piece on freezing seasons on lakes and rivers that was mentioned in the last para but not in any bullets. You may like to comment on this as some are x.x, some are y.y.y and some are z.z.z.z.

In the first case the whole section is really applicable and so mentioning each subsection does not seem worthwhile. Should we go to the z.z.z.z level, as that is not in the TOC?

In doing this I found that two sections in 3.8 had very similar titles and so I changed that of 3.8.3 to explicitly say tropical and extratropical storms and extreme events, which are the 3 subsections. The Table of contents (TOC) is all up to date, and now corrected for one subsection that was mislabeled as level 2 instead of 3.

Several figures have been revised.

I am out tomorrow all day but Lisa tells me she is up to w in the references. So should have a complete new version on Friday. Hopefully several of the figures will be by upgraded then too. I have a new Fig 3.3.1 but can't work with it: something wrong with it, so I've asked Dave E for a different one. Main outstanding stuff is all waiting on Dave Easterling. I have requests in to Tom Karl on the 2 CCSP figures.

Following my earlier email I have responses on Figs 3.2.3: now good, 3.4.6 I did, 3.5.2, and one from Groisman. So only 7 figures not in final form.

I believe we have 74 figures in the sense that they are separate files.

That includes counts of 1 for several multipanel files (like some T ones or the

Hi Peck and Eystein,

Here a reduced version of Box 6.2, taking into account suggestions from David and Bette. The text is now 1.5 pages, i.e. just slightly above target. The entire Box should now fit on less than 1 IPCC page (Assigned 0.75 page).

I am willing to take the next effort to shorten when the review comments of the FOD are in.

With best regards,

Fortunat

Cc: Keith Briffa <k.briffa@uea.ac.uk>

Simon,

If you go to this web page

[1]<http://www.ucar.edu/news/releases/2005/ammann.shtml>

You can click on a re-evaluation of MBH, which leads to a paper submitted to Climatic Change. This shows that MBH can be reproduced. The R-code to do this can be accessed and eventually the data - once the paper has been accepted.

IPCC will likely conclude that all MM arguments are wrong and have been answered in papers that have either come out or will soon. MBH is just one curve of many - more now than there were in 2001. MBH is still in the spaghetti of curves, and is not an outlier. If there are outliers it will be Esper et al. and another one.

Bristlecones are only crucial to the issue if you are MM. They misused them, by their PCA application. This is all well-known to those in the know.

I have reviewed the CC paper by Wahl and Ammann. It reproduces all the mistakes MM have made, so they know how and why their results have been achieved. I can send you the paper if you want, subject to the usual rules.

MBH have all responded to the same requests as IPCC got from the US Senate. Their responses are all posted at [2]<http://www.realclimate.org/>

The skeptics have shot themselves in the foot over this one.

Cheers

Phil

At 14:27 28/07/2005, Tett, Simon wrote:

John Houghton is being quized by bits of the US senate. One question is "Whats the status of the review of the Mann hockey stick temperature curve? I understand that studies by Stephen McIntyre and Ross McKittrick suggest that it relied on the statistically insignificant bristlecone pine. Is the IPCC taking another look at that work, which forms the basis for much of todays climate change debate?"

My current thoughts on an answer is to say that other reconstructions show a similar pattern (though not magnitude). However how many of the other reconstructions use the bristlecone data? [I suspect yours does

not]

Hi Simon - I was away yesterday, so couldn't answer then. Hopefully it isn't too late to answer today.

(1) I don't understand what they mean by describing the bristlecone pine as "statistically insignificant".

(2) The Mann, Bradley and Hughes (MBH1999) reconstruction is only one small piece of information in today's climate change debate.

(3) As far as I understand, then yes the MBH1999 reconstruction does give quite a lot of weight to a few western US tree-ring series, which are mostly bristlecone pines for the longest records.

(4) Other reconstructions show similar shape (though not magnitude) and support similar conclusions (regarding the unprecedented nature of recent warmth/warming trend). This is the main argument to make, as you thought. Some of these other reconstructions do not include these bristlecones (e.g. Briffa, 2000; Crowley et al., 2003; Moberg et al., 2005; Briffa et al., 2001). Crowley and Moberg use different Bristlecone records I think. Other reconstructions do use the same Bristlecone pines (e.g., Mann and Jones, 2004). BUT the critical thing is that the studies either do not use these Bristlecone pines, or if they do use them, then they give them much more similar weighting to the other records used. I think MBH1999 is the only one that might give them a dominant weighting.

(5) IPCC is assessing all published work that relates to these issues in preparation for the AR4 in 2007. This includes the McIntyre and McKittrick papers as well as papers that report results contrary to McIntyre/McKittrick, such as the paper in press by Wahl and Amman that shows the Mann et al. results are reproducible.

cc'd for additional comments to Phil and Keith (when he's back).

Cheers

Tim

Subject: Re: Out in latest J. Climate  
Date: Thu Aug 4 09:49:54 2005

Mike,

Gabi was supposed to be there but wasn't either. I think Gabi isn't being objective as she might because of Tom C. I recall Keith telling me that her recent paper has been rejected, not sure if outright or not.

Gabi sees the issue from a D&A perspective, not whether any curve is nearer the truth, but just what the envelope of the range might be.

There is an issue coming up in IPCC. Every curve needs error bars, and having them is all that matters. It seems irrelevant whether they are right or how they are used. Changing timescales make this simple use impractical.

We have a new version of HadCRUT just submitted, so soon the'll be HadCRUT3v and CRUTEM3v. The land doesn't change much. This has errors associated with each point, but the paper doesn't yet discuss how to use them.

I'll attach this paper. Only just been submitted to JGR - not in this format though. This format lays it out better.

Thanks for reminding Scott.

Cheers

Phil

Hi Phil,

Thanks for the heads up. Will be prepared for this then. I thought that Gabi Hegerl was involved with this guy? Doesn't she know better? It is disturbing that she hasn't set them straight on this.

By the way, as you may or may not have heard, its been discovered that there is a major error in Von Storch et al '04 that they now appear to be trying to hide (they have some obscure article in an Italian journal where they attempt to justify the error). There are several comments that have been or are soon to be submitted to Science about this. As it turns out, they introduces a spurious step in their supposed implementation of the MBH98 procedure in which they detrended the series first, gives completely wrong results.. Caspar Ammann and Gene Wahl and David Ritson of Stanford have both independently discovered this, because they noticed that amplitude of the calibrated signal in VS04 scales with the signal-to-noise ratio--this was the first clue that there was a major problem. There may be calls upon Science for them to retract their paper. The results are completely wrong, aside from the problems w/ the GKSS simulation. You

can expect to hear more about this soon...

I'll remind Scott about the proxies. He and Zhang are in the process of screening the proxy series for temperature signals, etc. Once they've done that, should be more useful. I expect we'll be able to get you some stuff by late August.

I did hear about the 3 papers coming out in Science. Apparently Donald Kennedy is doing an editorial that will discuss this in the context of the whole Barton business. That should be interesting...There will be articles by both Gavin and Steve Sherwood on "RealClimate" in coordination with the publication of the papers in Science Express. This should help turn the debate around.

talk to you later,

mike

Phil Jones wrote:

Mike,

He's been working with Myles Allen. Tim went to the first meeting of this Dutch funded project near Oxford last week.

Tim said they were doing some odd things, like correlating all the proxy series they had with CET (yes CET)! Even the few SH proxies they have. The others who went to the meeting were Zorita and Moberg. Zorita was still showing the GKSS run with Moberg series, even though its forcing is too large, it doesn't have aerosols in the 20th century and has spin up problems for the first 200 years.

Meeting wasn't that productive according to Tim. There was a belief amongst those there that all trees you used have lost low-freq, but this isn't true as you know.

Also, it was a good job Keith wasn't there (he didn't go as his father died the weekend before and he's not been in CRU since) as Martin assumed that RCS was developed by Esper (who also wasn't there). Tim put them right on this one, but RCS isn't applicable for normal tree sites, nor useful for bristlecones. Tim said Esper was wrong in his use of RCS, but they wouldn't accept that as Esper wasn't there to defend himself!

Basically only Tim knew anything about proxy data especially trees. Tim got the impression that they wanted to find that MBH is wrong. Given the previous comment, as you weren't there they are using double standards.

So, in conclusion, act carefully. Don't jump in, but some carefully thought through comments should be productive. Suggest they read the RevG article.

Martin isn't associated with the contrarians, but he's not in possession of the all the facts. He isn't aware of Casper's work, nor your latest study which you sent the other day, nor Rutherford et al.

There still seems to be a belief in these lower responding proxies. This is something we want to work on more here, as the only way it seems to show that these lower-freq proxies aren't that great is to use higher-freq proxies.

When you're back or sometime, can you remind Scott to send your

latest set of proxies. I'll have some time in the autumn to work on them as the AR4 should be in by Aug 12.

Science should be publishing 3 papers on the MSU issue by the end of Aug or early Sept. This is Mears/Wentz, Santer et al. and Sherwood et al. Latter shows that sondes are only truly reliable when flown at night. Daytime ones have all manner of problems with heating, just like air temps on board ships - hence the NMAT series.

I'll forward another email for interest.

Cheers

Phil

At 03:40 04/08/2005, you wrote:

Hi Phil,

Thanks, yes I'm in China now. As you might imagine, things have been very busy, but calming down a bit. Looks like Barton may be backing down...

Martin Jukes has an invited talk in my session. I invited him, because he was working w/ Stott et al, and so I assume he was legit, and not associated with the contrarians.

But if he's associated w/ the Dutch group, he may actually be a problem. Do you have additional information about him and what he has been up to?

Thanks,

mike

Phil Jones wrote:

Mike,

Good to hear it is out !

Hope the changeover is going OK and life is getting back to normal.

If you're not gone to China yet - you'll meet someone called Martin Dukes (?). He's giving a talk at your session. He knows about maths etc but not much about paleo ! Might need some education, but is probably OK. Not met him, but Tim has. Doing some worked funded by the Dutch govt on the hockey stick.

Cheers

Phil

At 04:05 03/08/2005, you wrote:

Dear Colleagues,

FYI, two papers attached:

First (reprint), Rutherford et al, is now out in latest issue of Journal of Climate.

This paper, aside from addressing other more scientifically-worthwhile issues, also happens to discredit most of the McIntyre and McKitrick claims.

Second (preprint), Mann et al, is formally in press (i.e., has gone off to the AMS production staff) in Journal of Climate. This paper strongly challenges the conclusions of von Storch et al (2004), and raises some methodological issues w/ the approach used

by Moberg et al (2005).

Feel free to pass along to others. Thanks

Mike

Hi Tim and Keith - Hope you're not going to kill me, but I was talking with Susan Solomon today, and she impressed me with the need to make several points if we can.

One issue (other to come in a subsequent email) is whether we can extend the MWP box figure to include the 15th century. I don't read the blogs that regularly, but I guess the skeptics are making hay of their being a global warm event around 1450AD. I agree w/ Susan that it is our obligation to weigh in on issues like this, so.... can we extend the fig to extend up to 1500AD?

Sorry about this, Tim. Of course we need it yesterday.

Thanks x10\*\*6

best, peck

Hi Tim - Decisions, decisions... thanks so much for taking the initiative. I think - for the reason you state, we should go for the one that includes the 20th century. We make clear that these are not reconstructed temp, but normalized anomalies - this keeps us out of some trouble. But, I think the main message is that we're looking at this issue from every angle. And, we're letting others see the issue from every angle. It adds punch.

this means that the MWP box needs to talk about the period around 1400 - can you make sure that's on Keith's radar screen. I believe that historians talk about the Medieval Period going to at least 1450, so what the heck...

I you can adjust the caption to work, and then send both it and the final fig to Øyvind, me and Eystein that would be good - make sure Keith is ok with it all first, too.

Thanks Tim! Best, Peck

Subject: RE: solar MM

Date: Mon, 8 Aug 2005 11:24:37 -0600

Cc: Keith Briffa <k.briffa@uea.ac.uk>, Eystein Jansen <eystein.jansen@geo.uib.no>

David - sounds promising. So, the bottom line is that a little disagreement is ok - that's a reflection of the real uncertainty? But, the discrepancy is not all that big in the end? No need to take this to a higher level?

Keith Briffa is back on line and finishing off Section 6.5, so you might want to send him an email w/ suggestions that help keep chap 6 compatible w/ 2 and 9 - for example, with respect to solar, we acknowledge the forcing could be less than  $0.5 \text{ W/m}^2$ , and the uncertainty wrt to trop aerosols and land albedo is significant - we could easily be closer to chap 9's estimate. Would you say the key is that our analysis acknowledge the uncertainty so as to overlap well with the other chapters?

Keith - please make sure you send your new 6.5 to David too - while you were out, he was working hard w/ chap 2 and 9 to make sure we (the IPCC) avoid saying things that confuse. The comparison of radiative forcings from 3 different angles is what assessment is all about, and it's great David has had the patience to help figure it all out.

Thx, Peck

Hi Gabi,

The key to your proposed solution is the updated numbers from Chapter 2. If indeed the radiative forcing change to 1750 is -1.53, then presumably you have made this consistent with the earlier part of Chapter 9. The numbers previously looked like this (I haven't seen the latest version of 6.5, but I've included the previous estimates we had in the ZOD):

$\text{W/m}^2$

	Chapter 6	Chapter 9
--	-----------	-----------

MM	1750	
----	------	--

Greenhouse gases:	-2.4	-2.6
-------------------	------	------

TROP aerosols:	0.5	0.2
----------------	-----	-----

Solar	-0.5	-0.1
Volcanic:	?	?
Land albedo:	+0.4	0.03
Trop O3:	-0.35	-0.4
Strat O3:	+0.15	0.10
1'st indirect aerosol forcing		1.2
STRAT H2O		-0.13
AVIATION		-0.02
TOTAL	-2.2	-1.7

There is essentially no change in greenhouse gas forcing from 1750 to 1700 (see for example Crowley et al., GRL, 2003), so the difference in the estimated numbers is probably due to inclusion of more things or different choices in Chapter 2. A similar statement holds for trop aerosols. One can also use these two to presume that the same also holds true for land albedo. [The value listed for that in Chapter 9 is quite small compared to some other studies; e.g., Govindasamy et al., GRL, 28, 291-294, 2001.] So, to the extent these numbers are still discussed in Chapter 6, they should be made consistent with those in chapters 2 and 9.

With respect to your proposed paragraph below: I would drop the comments about trace gas differences but saying land albedo changes may have been greater, along with the additional solar change, could give us the  $-1.8 \text{ W/m}^2$  forcing.

Concerning the temperature response: the Moberg et al paper itself claims  $1^\circ\text{C}$  difference between 1500 and 2000, but the figure seems to show a larger number, perhaps  $1.3^\circ\text{C}$  (again, just eye-balling it). However, the coldest time period is not in the MM but before it. I think therefore a better estimate from that paper for the MM would be  $1^\circ\text{C}$ .

So, with respect to the sensitivity: if  $0.85 \text{ W/m}^2$  is unresolved, then we have a total forcing of  $\sim 0.95 \text{ W/m}^2$ , and a climate response varying between  $0.45^\circ\text{C}$  and  $1^\circ\text{C}$  - or a climate sensitivity for  $2\times\text{CO}_2$  of  $1.9^\circ\text{C}$  to  $4.2^\circ\text{C}$ , or pretty similar to standard IPCC estimates.

I think this will work!

David

On Sat, 6 Aug 2005 hegerl@duke.edu wrote:

p.s. I modified the text for MM forcing according to below theory (please yell if its off!) which would say (and has questions for you): During the cool period of the Late Maunder Minimum (approximately 1675-1715), sunspots were generally missing, and solar irradiance is believed to have been smaller. This period will be used in Section 9.6 to discuss climate sensitivity; therefore we discuss its radiative forcing estimates . The estimated difference between present day solar irradiance and the late 17th century Maunder Minimum is presently -1.1 W/m<sup>2</sup> (best estimate, range -0.5 to -2 W/m<sup>2</sup> , Chapter 2), but with large

uncertainties. This leads to a best estimate radiative forcing of -0.2 W/m<sup>2</sup> (-0.1 to -0.35 W/m<sup>2</sup> 67% confidence interval; note that solar forcing from 1750 to the present is estimated having increased by 0.1 W/m<sup>2</sup> , chapter 2). Many radiative forcing changes, particularly those associated with industrialization, are very similar from the present to the Maunder Minimum as they are from the present to preindustrial (total forcing estimated of -1.53 W/m<sup>2</sup>, see 9.2.1.2). CO<sub>2</sub> may have been slightly lower (by???) , and land cover changes may also have been slightly greater between the Maunder Minimum and 1750. This yields an approximate net radiative forcing of -1.8 W m<sup>-2</sup> (between the late Maunder Minimum and the present, with large uncertainties.

OK. I agree with her on most. I was looking at the file over the weekend. The new 3.8.4 has helped as will the new ones on DTR when we get them. In the longer run I would like to get 3.7.1 and 3.7.2 redone - at least plotted better.

Also, in time, we will need to get the Sahel plot updated to have 2004 and 2005 in. Neil Ward was here for a few hours last week. He's now back at IRI, but he was surprised by the UK media and their reporting of the famine in Niger - saying it was all down to lack of rainfall. June in the region was above normal. Problems last year and locusts are the reason. The real reason may not matter on the ground, but the problems will recur as very little is planted this year.

Cheers

Phil

Thanks for the comments Jason/Henry. Just wanted to let you know that I've dropped the uncertainty ranges to be consistent with the other records and also cut the borehole series at the median sampling dates.

Cheers

Tim

At 16:45 04/08/2005, Jason E Smerdon wrote:

Hi Tim,

Henry and I apologize for not being available the last few days. Henry has been out of town and I have been in the midst of moving to New York. Nevertheless, we had the chance to cross paths today and discuss the figure and caption. We hope it is not too late to add our two cents.

We agree that the uncertainties on the borehole curves should be removed to make the display more consistent. We have also decided that it would be best to truncate the borehole curves at their median logging dates. For Australia and Africa those years are 1972 and 1986, respectively. If you wish to discuss the sampling densities, the total number of boreholes in Australia and Africa are 57 and 92, respectively. The SH has a total of 165 holes, compared to 695 in the NH.

Let us know if you need anything else. I hope this has not arrived too late and good luck with everything.

Best Regards,

Jason

Date: Tue Aug 9 14:34:59 2005

Dear all again,

here is the MWP figure and caption. Note that I don't know what number it should have, because it is for a box not a standard section. So I've just called it "mwpbox" for now. Please can you give it the correct number and put it in the right place in the figures file? Also, when you have numbered it, please let us know so that we can refer to it in the MWP box text.

The figure now goes right up to the present, as requested!

I've attached a word document with caption and .gif figure embedded, but also separate .gif, .pdf and .ps files for the figure. If you don't want all these different formats, then please tell me which one(s) you want and I'll only send those in future!

Cheers

Peck and Eystein

in case you tried (!), my phone has been broken for the last few days (yes - honestly). I am sorry I had to rush off - and stay longer than I had anticipated . The funeral was delayed

while a post-mortem examination had to be held to establish the precise cause of death.

Ironic

that dad had struggled on having had at least 3 heart attacks, 2 strokes, chronic diabetes and partial liver and kidney failure for some years (besides being virtually immobile and completely blind for 18 months). All in all , though it was a release, the actual demise was sudden and unexpected and I managed to arrive too late to be with him at the end. Given the time constraint , this "final" revision is not as considered as it might have been , but we have tried to take into account all comments available , and have given considerable attention to the IPCC terminology and emphasis on the bullet points . At this stage , however, there are some clear areas where future work will be required to keep abreast of recent developments and , perhaps, to re-balance the emphasis and structure. I apologise for not having responded directly to Fortunat, Stefan, Ricardo.Olga, David and Tom, but please be aware that I have considered all of their comments and done what I could to address them .Thanks Fortunat and Ricardo (and Ed - who should be added to the list of CAs) for the text and Figures and Henry and Jason for the help and data . David's suggestions about re-ordering the paragraphs was particularly difficult to resolve in my own mind , because I do see the logic , but equally , did not want to interfere with the time line approach to describing post- TAR work that underlies the current structure. as you can see I decided to leave the order as it was. It would be great if David and Fortunat could check cross Chapter referencing (eg in relation to forcings and detection chapters). We can revisit this , and the issue of McIntyre and McKitrick (centering of PCs in Mann et al reconstruction - which is clearly unfounded) until such time as the numerous responses are published.

The new SH section is in , and the MWP box slightly amended to take account of the new Figure.

Peck, I have considered your text on the regional section - and you will see that I have edited out some relating to future (and association between drought and SSTs) . I feel strongly that you are venturing into "observational" territory and speculation beyond what we should say. I have also amended the bullet points to reflect this. **YOU ARE THE ULTIMATE ARBITERS** and it is up to you if you wish to re-insert , but I will give you a continuing argument later about our overstepping the "paleo" boundary. Note also that the bullet on European summer 2004 has been altered to reflect what was a last minute , one-sentence , insertion in the first paragraph regarding Jurg Lutterbacher's Science paper - as there was

no mention of it otherwise. We had to remove the reference to "700 years in France" as I am not sure what this is , and it is not in the text anyway. The use of "likely" , "very likely" and my additional fudge word "unusual" are all carefully chosen where used. Tim has been a rock in the last minute rush here - not only doing the Figures , but also helping with the text. I am really grateful to him. He has sent the text , with some comments, and highlighted references, that need attention. If Oyvind can identify references and handle these problems with Endnote , we are also really grateful. The final references , if missing , are probably in the current text, the previous Endnote library , or in sections of text sent by Ricardo, Fortunat, Peck and Eystein. I trust when you guys have stiched the new text back in and the Figures etc. we will perhaps get a last chance to correct and check references etc. Thanks

Keith

Peter, Kevin

Not having seen Ch 4, I agree that the term 'local heat budget' can be ambiguous. Are you also discussing the issue of 'dirty' glaciers? For the Alps, the Swiss (well Wilfried Haeberli) reckon that temperature alone cannot explain all the retreat in some recent summers (especially 2003). Would local heat budgets include the effects of local anthropogenic pollutants making the snow less white?

Lonnie Thompson has been on Quelccaya in the last couple of months and reports that it is in an awful state. Like Kilimanjaro, the recent annual layers aren't distinguishable. Lonnie reckons a lot of retreat is caused by sublimation. On Quelccaya Lonnie and Ray Bradley have put up an AWS (on Sajama too). They've not got as much data as they hoped as both have fallen over due to melting and also the guide who helped them put one on Quelccaya later went back and brought it back down to try and sell !

I'm happy with Kevin's draft, if local heat budgets is explained in your chapter.

Cheers

Phil

At 17:29 09/08/2005, Kevin Trenberth wrote:

Peter, Thanks (sorry I can't get rid of the blue).

I am cc'ing Phil on this: Georg has suggested instead the following.

The temperature increases are consistent with the observed nearly worldwide reduction in glacier and ice cap mass and extent with strongest recession rates in the 1930s and 1940s and after 1990 and little changes around 1970. Tropical glacier changes are synchronous with global ones, Kilimanjaro being an exception with radiatively forced constant retreat of the plateau ice. 20<sup>th</sup> Century glacier retreats are consistent with temperature variations. Before 1900, glacier fluctuations are probably not only reflecting temperature variations but mainly precipitation anomalies. In the Tropics, glacier changes are related to atmospheric moisture variations which, in turn, correlate with sea surface temperatures in the respective source regions and varying atmospheric circulation modes. In some regions (Alaska, Patagonia, Karakoram) moderately increased accumulation is observed indicating an amplified hydrological cycle.

I am not altogether happy with this wording. In this bullet it reflects findings from your chapter and ours (wrt precip, temp, circulation etc). I would propose the following as a compromise between the old text and the proposed:

The temperature increases are consistent with the observed nearly worldwide reduction in glacier and ice cap mass and extent in the 20th century. Tropical glacier changes in South America, Africa and Tibet are synchronous with global ones, and all have shown

declines in recent decades. If continued, some may disappear within the next 30 years. Local temperature records all show a slight warming, but not of the magnitude required to explain the rapid reduction in mass of such glaciers (e.g., on Kilimanjaro), which instead depends on local heat budgets. Glaciers and ice caps respond not only to temperatures but also changes in precipitation, and before 1900, glacier fluctuations are probably not only reflecting temperature variations but mainly precipitation anomalies. In some regions moderately increased accumulation observed in recent decades is consistent with changes in atmospheric circulation and associated increases in winter precipitation (e.g., southwestern Norway, parts of coastal Alaska, Patagonia, Karakoram, and Fjordland of the South Island of New Zealand).

Note I have retained a bit more detail on the regions affected, and tried to stay away from "radiatively forced" (whatever that means) and vague terms like "amplified hydrological cycle". I also want to retain more specific reference to the precip and circulation changes going together. Whether "local heat budgets" is adequate is my main question? I gather this is related to changes in cloud and sunshine, increased heating that goes into melting and ablation rather than temp increases. Should we spell that out? Do you deal with that? I also did not add the detail on the dates in first sentence as those should be in your chapter and they don't relate directly to the other variables.

Are my terms "20th century" and "recent decades" correct?

Thanks

Kevin

Peter Lemke wrote:

Dear Kevin,

after his return from the Kilimanjaro Georg has supplied a modification to the text in 3.9 concerning the glaciers.

I have made a tiny change further down in the text replacing "order" by "approximately" meaning 1mm/year and not implying, say, 3mm/year.

Best regards,

Peter

Fine with me. Let's hope they agree by tomorrow.

Phil

At 17:11 10/08/2005, you wrote:

Ok so here is how it now reads:

The temperature increases are consistent with the observed nearly worldwide reduction in glacier and ice cap mass and extent in the 20<sup>th</sup> century. Tropical glacier changes in South America and Africa, and those in Tibet are synchronous with higher latitude ones, and all have shown declines in recent decades. Local temperature records all show a slight warming, but not of the magnitude required to explain the rapid reduction in mass of such glaciers (e.g., on Kilimanjaro). Glaciers and ice caps respond not only to temperatures but also changes in precipitation, and both global mean winter accumulation and summer melting have increased over the last half century in association with temperature increases. Other factors in recent ablation include changes in cloudiness and water vapour and associated radiation, and surface sensible heat exchange. Precipitation anomalies are also important before 1900 in glacier fluctuations. In some regions moderately increased accumulation observed in recent decades is consistent with changes in atmospheric circulation and associated increases in winter precipitation (e.g., southwestern Norway, parts of coastal Alaska, Patagonia, Karakoram, and Fjordland of the South Island of New Zealand) even as enhanced ablation has led to marked declines in mass balances in Alaska and Patagonia.

Kevin

Phil Jones wrote:

Sort of arguing that way. It is also the before 1900 part. Precip and temp anomalies are important at all times for glaciers. Their influence didn't change around 1900.

So what about Precipitation anomalies are also important before 1900.

I'd not got the implication. Adding also makes it clearer.

Phil

At 16:56 10/08/2005, Kevin Trenberth wrote:

Phil is arguing for changes to 4.5. Maybe the statement is too strong although it is consistent with the last para of 4.5.2.? An alternative might be: Precipitation anomalies are important before 1900. In the context this implies in addition to temperature.

Kevin

Phil Jones wrote:

Georg,

I've now also looked at the figures you sent from Ch 4. Kevin has the sentence, which Peter may have added? I reckon this is too strong. Can we omit it?

Sentence is

Before 1900, glacier fluctuations probably mainly reflect precipitation anomalies.

Reasoning

Is this a general statement. I wonder if we need it. Oerlemans uses estimated glacier termini positions (and related ELA changes) to infer past temperatures and you have his figure. I know he assumes precip to have remained essentially the same but he backs out temperature. Also glaciers in Europe advanced in the 17th and 18th centuries. It was cooler then (more so in winter than summer). I also have a paper resubmitted to JGR where Alpine precip shows no long-term changes since 1800. This uses loads of stations and is from the ALP-IMP project that ZAMG co-ordinate (Reinhard Boehm).

So the advances are caused by more precip, but the retreats by higher summer T and maybe less winter precip.

Cheers

Phil

At 16:23 10/08/2005, Kevin Trenberth wrote:

Hi Georg

Many thanks for the attachments. I had looked at the ZOD but this is much more informative. Based on your comments and the 4.5 section I have come up with the following bullet. Note that here we are writing for a general audience. I have now tried to include more clearly the factors involved. I think these are consistent with your chapter but the language in your chapter might be improved in a couple of places. For instance an important forcing is radiation (solar and IR) which are greatly impacted by clouds, water vapor, and albedo (the dirty cover on top of snow Phil referred to), and I thought these could be brought out better in your chapter. These are perhaps more basic than temperature lapse rates and precipitation gradients which are consequences. In 4.5.2 you use the term "radiatively forced" but it is not clear what that means. I suggest using some of these terms. Also it is not clear what "amplified hydrological cycle" means. [FYI, the expectation is for more intense precipitation, not necessarily for more total (owing to pollution effects). The former is determined by increased water vapor]. I took some of your words in the following. We need to emphasize that glaciers are not just high latitudes. I retained Kilimanjaro as that has received a lot of publicity. Some of this is necessarily abrupt, but there will be a reference to 4.5 immediately following this bullet. So the recent reversals in NZ and Norway can not be dealt with here.

Let me know if you have further suggestions. Again, many thanks

Regards

Kevin

o The temperature increases are consistent with the observed nearly worldwide reduction in glacier and ice cap mass and extent in the 20<sup>th</sup> century. Tropical glacier changes in South America and Africa, and those in Tibet are synchronous with higher latitude ones, and all have shown declines in recent decades. Local temperature records all show a slight warming, but not of the magnitude required to explain the rapid reduction in mass of such glaciers (e.g., on Kilimanjaro). Glaciers and ice caps respond not only to temperatures but also changes in precipitation, and both global mean winter accumulation and summer melting have increased over the last half century in association with temperature increases. Other factors in recent ablation include changes in cloudiness and water vapour and associated radiation, and surface sensible heat exchange. Before 1900, glacier fluctuations probably mainly reflect precipitation anomalies. In some regions moderately increased accumulation observed in recent decades is consistent with changes in atmospheric circulation and associated increases in winter precipitation (e.g., southwestern Norway, parts of coastal Alaska, Patagonia, Karakoram, and Fjordland of the South Island of New Zealand) even as enhanced ablation has led to marked declines in mass balances in Alaska and Patagonia.

Georg Kaser wrote:

Kevin,

Have many thanks for compiling and editing 3.9. I agree that the "radiatively forced" and the "amplified hydrological cycle" should be removed and I also agree with Phil's comment on the "local heat budget". In glaciology, the sum of each energy flux toward and from the respective snow/ice surface is considered to make up the "local heat budget". This also includes the sensible heat flux.

There are some other points in the text which I would like to comment:

1. Tropical glaciers are considered those in the South American Andes between Venezuela and Northern Bolivia, those in East Africa and those in Irian Jaya (New Guinea). In Chapter 4, Tibetan glaciers are taken as part of the Asian High Mountains (find the present state Chapter 4.5. "Glaciers and Ice Caps attached).

2. Alaska, Patagonia, Karakoram, Norway and NZ cannot be merged in the respective statement. In Alaska and Patagonia, moderately increased accumulation is accompanied by strongly enhanced ablation making the mass balances markedly negative. From glaciological sites, no studies concerning atmospheric circulation patterns are provided in the respective studies.

In the Karakoram mountains, enhanced accumulation has led to considerable glacier advances, increased winter accumulation from the Westerlies is only suggested but not subject of detailed studies. Heavy debris loads on the tongues probably prevent from enhanced ablation.

In Southwest Norway and NZ South Island, glacier advances have ceased around 2000. I don't know whether their advances shall still be mentioned in extension; I would not do so beyond the respective statement in Ch. 4.5.

3. "If continued, some may disappear within the next 30 years." This sentence can stand

for every mountain region in the world and should not be used for tropical mountains only. Everywhere, many small glaciers have disappeared since the 19th Century maxima and many will disappear soon in the Alps, the Caucasus, in the Asian High mountains etc. as well as in the Tropics. From the today's perspective Mount Kenya, all Mountains in the Rwenzori Range except Mt. Stanley, Irain Jaya will be without glaciers soon, probably sooner than Kilimanjaro; well known and studied glaciers in the Andes like Chacaltaya, Charquini and Pastoruri will also disappear soon. This is not because of a particular regional climate feature but just because they were already small when retreats started. As you will see from Figure 4.5.5. Kilimanjaro's plateau ice is particular, slope glaciers are less. The plateau glaciers retreat from their vertical walls where no accumulation is possible and since they do so, there is no way to find an equilibrium besides disappearance. The vertical walls are a result of cold temperatures high sublimation and strong solar radiance. There is no way to replace the retreat by ice dynamics on the flat summit plateau. Slope glaciers are only partially subject of this kind of ablation and their retreat rate seems to have slowed markedly (See insert of Fig 4.5.5). If Kilimanjaro is mentioned in 3.9. it must also be added that it is a particular case with complex relation to climate change.

4. All studies which investigate tropical glacier retreat and climate show the dominance of changes in energy and mass balance terms which are related to the atmospheric moisture content rather than locally measured air temperatures. Both increased and reduced moisture can lead to negative mass balances and it has done so in most cases studied (Cordillera Blanca, Peru, Cordillera Real, Bolivia, Antisana, Ecuador, Rwenzori, Mt. Kenia, Kilimanjaro). Yet, wherever respective analyses were made, correlations were found to anomalies in ENSO or Indian Oceans Indian Ocean Dipole Mode respectively strongly indicating global warming as the principle reason of the retreat.

I give you this lengthy explanation in order to make sure that the very compressed and condensed bullet in 3.9. gets the right content. I have started to change your paragraph suggestion accordingly but have to admit that, not being a native speaker myself, it either becomes very long or very awkward.

I also appreciate Phil's statement about Quelccaya and Sajama. Doug Hardy and Ray Bradley run AWS' there since a couple of years as well as on Kilimanjaro with all the problems of recording data at such high elevation sites. Doug is preparing a paper on the climate records there but it has still not reached it's final state.

Information on sublimation on Quelccaya is not published such as the positive mass balances and advances on several Andean glaciers between 1998 and 2002 are not published. Kilimanjaro has experienced both ablation as well as accumulation layers on the horizontal surfaces over the last years. I have just come back from fieldwork there last week and the last half year was a mass loss year. Being very much involved into tropical glaciers myself, I have to accept that such detailed information would be available for several hundreds of glaciers in the world each one providing 10 or more publications. Going into such details cannot be the aim of the report, I am afraid.

Best wishes,  
Georg

Hi Caspar,

Thanks for the comments. Frankly, Von storch is being duplicitous here. He may tell certain audiences (like the NCAR group last month) that he is not suggesting that the GKSS simulation is realistic, because he knows he'll get skewered if he claims otherwise. But then he turns around to the press, and talks about how the Moberg et al reconstruction matches their model, etc. I frankly consider this dishonest, at best!

If what Stefan says is true (that the entire long-term trend, including the cold LIA in the model, is all due to the spinup problem), then it completely invalidates the use of that model for testing statistical reconstruction methodologies which require physically-consistent patterns of variance in the calibration period to reconstruct the past. But that's a separate issue.

As we now know, the far more damning fact is that Von Storch et al knowingly applied a procedure which is not the MBH98 procedure, and they think they can get away w/ admitting this now in some obscure Italian journal which isn't even in the ISI database. Tim/Phil/Keith: you may not know about the latter, but Caspar should be able to fill you in on this shortly...

Meanwhile, lets enjoy the media fiesta on MSU...

Mike

Hi Phil,

Yeah--I've been told that one of the co-authors of the chapter (w/ the initials D.R.) has behaved poorly. Fortunately, w/ Peck, Stefan R., and Keith all authors on the chapter, it sounds as if the voices of reason are prevailing...

mike

Phil Jones wrote:

OK. Keith is also away next week. He's already gone.

He'll need to look more at all this before the next IPCC meeting in December.

You should have seen some of the crap comments he got. Not yours, but some of the other authors on the paleo chapter.

People who you think ought to know better. Most relating to MM. All mostly ignored. You'll be able to register to get the draft by early Sept.

Cheers

Phil

At 16:49 12/08/2005, you wrote:

Thanks Phil,

Can you tell Keith (confidentially) that Ammann and Wahl are submitting a comment to Science pointing out that von Storch knowingly did not apply the MBH98 procedure, and that all of the conclusions in that paper are wrong! There may be calls on Science to retract VS04, because the mistake undermines every single conclusion!!

mike

Phil Jones wrote:

Mike,

We have the Italian paper Well Keith does for his AR4 work.

Submission day for AR4 is today by the way.

I think the Italian journal is the one from a conf I went to 3 weeks after the Berne meeting. I didn't bother sending anything to the Italian meeting either, just like Berne. The journal the Italians were planning did look obscure when I was there, but I didn't write anything down, as I had no intention of sending anything.

Yes the MSU stuff is out. There will be something in Nature next week on it.

Off next week as a break from IPCC.

Cheers

Phil

Hi Mike,

here is some interesting new info on the drift problem in the VS04 runs. Irina Fast and Gerd Bürger submitted a comment about this to Science some months ago; it was rejected and they did not pursue it. I'm trying to encourage them to resubmit this elsewhere. I do not have the ms. but have seen several graphs. There are two key points.

1. The ECHO-G run started at year 900, the VS04 paper of course shows only results starting from year 1000. I've seen the full run now. Between 900 and 1000, the NH temperature drops by about 1.5 °C! That's how severe their initialisation problem is. From my experience of how the THC responds after such step-function changes in forcing, the strong warming from 1050-1150 in VS04 could well be a rebound effect from the 1.5 °C cooling that precedes it, since the THC tends to oscillate on such a time scale when forced rapidly.

2. Irina has run ECHO-G initialised with modern climate and then switching to pre-industrial conditions similar to the run shown by VS04, but without any further variability in the forcing. Thus, this shows the pure drift from initialising this run - this is what Tim has been estimating in MAGICC. The actual drift in ECHO-G is even larger and more persistent than what Tim found: there is a cooling between the years 1000 and 2000 of over 0.6 °C, and this is an almost linear trend over the whole time.

I.e., not just drifting during the first few centuries, but over the entire 1000-year period.

Cheers, Stefan

Date: Mon Aug 22 16:22:28 2005

Ben and Tom,

Congratulations on the paper coming out on Aug 12.  
I did talk to Nature about the three papers.

Last week seems to have been a good one to have had off.  
I did this because of the IPCC submission deadline of Aug 12.  
As you said Tom, there were some stupid messages going  
around. If only these people would try and write peer-review  
papers, provided they get proper reviews. The one from  
Sonia should be kept as it proves that E&E is not a  
proper journal.

I almost missed the one with Pielke's resignation in. Is this  
going to make your CCSP task easier or harder? Presumably  
now you'll get all his comments to officially deal with. Maybe  
you'll be able to ignore them?

Cheers

Phil

Christoph,

It also looks OK to me. The bit highlighted in blue, should probably say something like ...identify the key issues.

I agree with Mike that the last two names on the list should be removed.

I have sent an email about the 4th meeting of IPCC, which I think is June 26-30, 2006. Just checking it is still that week, so there won't be a clash.

Cheers

Phil

Dear Phil et al,  
I agree on Mike Evans. I'm afraid I don't agree on Zorita. He has engaged in some very nasty, and in my opinion unprofessional email exchanges with some close colleagues of mine who have established some fundamental undisclosed errors in work he co-published with von Storch. Given this, I don't believe he can be involved in constructive dialogue of the sort we're looking for at this workshop. There are some similarly problematic issues w/ Cubasch, who like von Storch, who has engaged in inflammatory and ad hominem public commentary. There is no room for that on any side of the debate. If the Germans need to be represented here, I would suggest instead someone from the Potsdam group, such as Eva Bauer, who has been doing some very interesting work on modelling the climate of the past 2K,  
mike

I have checked with IPCC and their 4th meeting is in the June 26-30 week in Bergen..  
As for Heinz's suggestions  
- Mike Evans would be OK  
- I'm nor sure that Mikami would contribute much  
See Keith's comment on Zorita  
Cheers  
Phil  
At 14:39 26/08/2005, Heinz Wanner wrote:

Dear Christoph,  
  
I have only a few additional comments concerning the planned workshop.  
  
First of all, I support this concept. Related to the topics, I heavily support to organize a discussion about how we can reconstruct different parameters independently.

It is important to try to reconstruct air pressure as a basic circulation parameter - if possible.

Concerning the participants:

- Write GooSSe;
  - Mikami from Japan (Tokyo Metropolitan University) could be an interesting Asian participant;
  - You mentioned Kevin Trenberth or Mark Cane. Both are absolutely okay, but why not invite a younger colleague like Mike Evans from Tucson?
  - If Phil and Mike do not support von Storch it does not make sense to invite him (and Eduardo Zorita?);
  - For me Ulrich Cubasch is an interesting modeler with good ideas about paleomodeling.
- Maybe Gavin can comment this when he is back from his China trip?

Cheers, Heinz

Tom,

Can you crossdate these two series (trw and mxd) for the Polar Urals?  
Particularly check the 1032 value when only 3 samples.

Found this on the blogg site that Tim sent round. Whatever you do,  
don't respond on the blogg.

Cheers

Phil and Keith

Dear Eystein and Peck

Following the release of the first draft of the WG1-AR4 we have had a response from Steve McIntyre (a name that should ring a bell) regarding unpublished literature in Chapter 6. He also asks about access to data sets but that is not an IPCC function so is easily dealt with.

The unpublished papers that he has picked up as not being available are:

Briffa, K.R., T.M. Melvin, V.V. Shishov, and et. al, 2005: Warm season temperatures across northern Eurasia: a 2000-year tree-ring based study. Quaternary Science Reviews(In preparation).

and

Wilson and al. 2005 (mentioned on page 6-31)

The first of these was I think meant to be deleted from the text here and we may have made an error in missing that. The second is cited but does not appear in the reference list so we did not pick it up as an unpublished paper that needed to be collected.

Could you please let me know:

- 1) are drafts for either of these papers available yet and if so can you send copies to the TSU?
- 2) how do you expect to use these references in the second draft - remembering that we can only use papers that are in press at that time and that the Briffa et al paper is used quite a bit - e.g. on page 6-29.

I am attaching the correspondence with McIntyre below for your information but the only issues you need to consider are those above, and we will handle any further interactions with McIntyre from here.

Thanks

Martin

It's possible that the references were inadvertently left in, in which case your suggestion that a comment be pointed on the review form would obviously suffice. However, it's equally possible that the authors intend to use these references and they inadvertently failed to post them up on the website. If the latter, then they should ask the authors to post up the references. Could you verify which applies with the authors and, if the latter, take appropriate steps.

Additionally, I have attempted to locate van Ommen, Annals of Glaciology, 39, mentioned in the same section. Can you confirm that this volume has either been printed or made available electronically (as I am presently unable to locate wither). If not, then this should be made available in a pdf form at the website.

I have been unable to locate supplementary information or data archives for several of the articles posted at the pdf location for Chapter 6 and would appreciate assistance in this regard.

1) Hegerl et al, submitted. Can you provide me with an ftp location for the proxy data used in this study (which does not even list the proxies used) or post it at your website.

2) D'Arrigo et al, submitted. Again, this data has not been archived at WDCP. Can you provide me with an ftp location for the proxy data used in this study or post it at your website.

Similarly, the SI to Rutherford et al, 2005 does not contain the Briffa et al. data set. Again can you provide an ftp location for this dataset or otherwise provide it.

Thank you for your attention, Steve McIntyre

Dear Dr McIntyre,

It would seem that the authors may have inadvertently left in the Wilson et al. and Briffa et al. citations, as I do not have copies of the preprints for either. I apologize for the discrepancy and have made note of this error for the authors for correction of the next draft, but if you would also like to comment on this in your review, please do so.

Best regards,

Melinda Tignor

Steve McIntyre wrote:

Thanks for the directions. I found 5 of them there. I was still unable to locate Briffa et al, 2005 (QSR in prep) or Wilson and al. 2005 (mentioned on page 6-31). Could you take a look for them. Thanks.

To: [8]Steve McIntyre

Sent: Monday, September 19, 2005 4:58 PM

Subject: Re: Chapter 6 - Submitted Papers

Dear Mr McIntyre,

As mentioned on the Reviewer website, copies of unpublished literature may be downloaded for your review. Papers for each chapter are found at the same website:

URL: [9]<http://ipcc-wg1.ucar.edu/restricted/review/FOR/>

UserName: WG1-FOR

Password: 2005Nov04

Once inside the site, click on "Download Draft Chapters" on the left side of the page.

From here, scroll down the page where you downloaded the chapter to the last sentence,

"If you wish to see copies of unpublished papers cited in the draft chapters click here"

- click "here" and you will be taken to another page listing all the chapters with

unpublished literature and from clicking on the individual chapter you will be taken to

the list of unpublished literature.

Please let me know if I can be of further assistance.

Best regards,

Melinda Tignor

WGI TSU

Steve McIntyre wrote:

Dear Sirs,

The covering literature indicated that the website would provide access to submitted, in-press, or otherwise unpublished papers and reports that are cited in the draft WG I report. In connection with Chapter 6, I was unable to locate the following:

Briffa et al, 2005. (presumably this is the paper denoted as in prep. in the bibliography)  
D'Arrigo et al, submitted  
Hegerl et al, submitted  
Smerdon et al 2005. JGR (in review)  
Tett et al, submitted. Clim. Dyn. submitted.  
Wahl and Ammann 2004. (in review)  
Wilson and al, 2005 (referred to on page 6-31, but not in bibliography).

Could you please post these on the website or email me pdf's. For these unpublished articles, could you also provide locations of FTP sites where the underlying data may be reviewed.

Thank you for your attention,  
Stephen McIntyre

Dear Phil, Eystein and Peck,

I've already talked about this to Phil and Keith, but for Eystein's and Peck's benefit the emails copied below relate to McIntyre downloading a PDF of a manuscript cited by the IPCC paleo chapter and then apparently trying to interfere with the editorial process that the paper is currently going through at JGR.

I think this is an abuse of McIntyre's position as an IPCC reviewer.

Rosanne replied to my email below, to say that they **do** want this taken further. So...

Phil has agreed to forward these messages to Susan Solomon and Michael Manning.

Eystein and Peck: do you want to add anything too?

Cheers

Tim

thanks for this. When time allows we will do a response to this poster and simply post it on our web page. As others have said, the dating of the chronology in the Urals is not wrong - but the magnitude of the extreme years in the early Urals reconstruction were not adjusted to account for inflated variance related to low chronology replication - so they are sort of right that the emphasis on 1032 is probably overdone.

Anyway thanks again

Keith

At 15:29 15/11/2005, Michael E. Mann wrote:

Thanks Tim, Phil

yes, I never had any doubt he's wrong. In fact he's been wrong about just about every claim he's ever made. He almost had a point w/ the PCA centering, but as we all know, that doesn't matter at all in the end. The issue isn't whether or not he's right, as we all well know by now, but whether his false assertions have enough superficial plausability to get traction. In this case, they might, so probably good to at least be prepared.

I was told by a journalist Paul Thacker that his poster got prominent placement, probably not an accident (see forwarded email). I believe that Mike Schlesinger and David Karoly were there in the same session, so might be worth checking w/ them. I think Connie Woodhouse and Tom Wigley were also at the meeting, but not sure...

I suspect that this is the first in a line of attacks (I'm sure Tom C is next in line) that will ultimately get "published" one way or another. The GRL leak may have been plugged up now w/ new editorial leadership there, but these guys always have "Climate Research" and "Energy and Environment", and will go there if necessary.

They are telegraphing quite clearly where they are going w/ all of this...

Mike

Tim Osborn wrote:

Thanks for this Mike. We'd spotted an earlier draft of his poster and were a bit concerned about this receiving prominence at the meeting.

Did it arouse much discussion, do you know? Keith and Tom Melvin looked into the dating a while back when McIntyre first raised it and were quite satisfied with the published dating I think. Not sure what should be done - unless he submits something for peer-review. Cheers, Tim

More on Hockey Sticks: The Case of Jones et al. [1998]

Stephen McIntyre, <[2]mailto:stephen.mcintyre@utoronto.ca>stephen.mcintyre@utoronto.ca

Multiproxy studies purporting to show 20th century uniqueness have been applied by policymakers, but they have received remarkably little independent critical analysis.

Jones et al. [1998] is a prominent multi-proxy study used by IPCC [2001] and others to affirm the hockey stick shaped temperature reconstruction of Mann et al. [1998].

However, the reconstruction of Jones et al. [1998] is based on only 3-4 proxies in the

controversial Medieval Warm Period, including non-arms-length studies by Briffa et al. [1992] and Briffa et al [1995]. We show that the Polar Urals data set in Briffa et al [1992] fails to meet a variety of quality control standards, both in replication and crossdating. The conclusion of Briffa et al. [1995] that 1032 was the "coldest year" of the millennium proves to be based on inadequate replication of only 3 tree ring cores, of which at least 2 are almost certainly incorrectly crossdated. We show that an ad hoc adjustment to the Tornetrask data set in Briffa et al [1992] cannot be justified. The individual and combined impact of defects in the Polar Urals data set and Tornetrask adjustments on the reconstruction of Jones et al [1998] is substantial and can be seen to have the effect of modifying what would otherwise indicate a pronounced Medieval Warm Period in the proxy reconstruction. Inhomogeneity problems in the Polar Urals and Tornetrask data sets, pertaining to altitude, minimum girth bias and pith centering bias will also be discussed.

fair enough, I'll go w/ flimsy. The real problem is the fairly inflammatory wording of this, and the really flawed interpretations w.r.t. implicatinos for natural vs. anthropogenic variaibility.

normally I'd ignore, but the fact that Andy Revkin received this suggests they are trying to publicize this review paper, which I find a bit odd...

>>> Abstract

>>>

>>> Comparison of large-scale temperature reconstructions over the past

>>> millennium reveals agreement on major climatic episodes, but

>>> substantial divergence in reconstructed (absolute) temperature

>>> amplitude. We here detail several research priorities to overcome

>>> this 'amplitude desideratum', and discuss the relevance of this

>>> effort for the prediction of future temperature changes and the

>>> meaning of the Kyoto protocol.

>>>

>>> Persisting controversy (Regalado, 2005) surrounding a pioneering

>>> northern hemisphere temperature reconstruction (Mann et al., 1999)

>>> indicates the importance of such records to understand our changing

>>> climate. Such reconstructions, combining data from tree rings,

>>> documentary evidence and other proxy sources are key to evaluate

>>> natural forcing mechanisms, such as the sun's irradiance or volcanic

>>> eruptions, along with those from the widespread release of

>>> anthropogenic greenhouse gases since about 1850 during the

>>> industrial (and instrumental) period. We here demonstrate that our

>>> understanding of the shape of long-term climate fluctuations is

>>> better than commonly perceived, but that the absolute amplitude of

>>> temperature variations is poorly understood. We argue that the

>>> knowledge of this amplitude is critical for predicting future

>>> trends, and detail four research priorities to solve this

>>> incertitude: (i) reduce calibration uncertainty, (ii) preserve
>>> 'colour' in proxy data, (iii) utilize accurate instrumental data,
>>> and (iv) update old and develop new proxy data.

>>>
>>> When matching existing temperature reconstructions (Jones et al.,
>>> 1999; Mann et al., 1999; Briffa, 2000; Esper et al., 2002; Moberg,
>>> et al., 2005) over the past 1000 years, although substantial
>>> divergences exist during certain periods, the timeseries display a
>>> reasonably coherent picture of major climatic episodes: 'Medieval
>>> Warm Period', 'Little Ice Age' and 'Recent Warming' (Fig. 1).
>>> However, when calibrated against instrumental temperature records,
>>> these same reconstructions splay outwards with temperature
>>> amplitudes ranging from 0.4 to 1.0 °C for decadal means (Moberg et
>>> al., 2005). Further, a comparison of commonly used regression and
>>> scaling approaches shows that the reconstructed absolute amplitudes
>>> easily vary by over 0.5 °C, depending on the method and instrumental
>>> target chosen (Esper et al., 2005). Overall, amplitude discrepancies
>>> are in the order of the total variability estimated over the past
>>> millennium, and undoubtedly confuse future modelled temperature
>>> trends via parameterisation uncertainties related to inadequately
>>> simulated behaviour of past variability.

>>>
>>> Fig. 1. Course of temperature variations. Large-scale temperature
>>> reconstructions scaled to the same mean and variance over the common
>>> period 1000-1979 AD, and their arithmetic mean. The normalisation
>>> highlights the similarity between the records, but broadly ignores
>>> the differing calibration statistics with instrumental data, and
>>> their particular 'shapes' and distribution of variance, e.g. during
>>> the instrumental and pre-instrumental periods. The average
>>> correlation between the original reconstructions is 0.47, and 0.64
>>> after smoothing (as done in the figure using a 40-year low-pass
>>> filter). Lag-1 autocorrelations range from 0.52 (Jones98) to 0.93
>>> (Moberg05; with no variability <4 years represented).

>>>
>>>
>>> Solutions to reduce calibration uncertainty include the use of
>>> pseudo-proxy experiments (Osborn and Briffa, 2004; von Storch et
>>> al., 2004) derived from ensemble simulations of different models
>>> (Knutti et al., 2002; Stainforth et al., 2005) to test statistical
>>> calibration methods, e.g. principal component (Cook et al., 1994)
>>> and timescale-dependent (Osborn and Briffa, 2000) regression. Such
>>> analyses, however, should mimic the character of empirical proxy
>>> data, e.g. the decline of replication (numbers of sites, quality per

>>> site) back in time, and the addition of noise typical to empirical
>>> proxy data (i.e., not just white; Mann and Rutherford, 2002).
>>> Further, reconstructions from areas such as Europe (Luterbacher et
>>> al., 2004; Xoplaki et al., 2005), where long instrumental series and
>>> high densities of proxy records exist, allow extended calibration
>>> periods and increased degrees of freedom enabling the assessment of
>>> robust relationships at all timescales (i.e., low and high
>>> frequency), both critical to reduce calibration uncertainty.
>>> Subsequent comparison of such regional records with hemispheric
>>> reconstructions that can be downscaled should provide greater
>>> understanding of reconstructed amplitudes at larger spatial scales.
>>>

>>> Accurate preservation and assessment of low-to-high frequency
>>> variation ('colour') in proxy data, and a selected use of certain
>>> frequency bands that best fit those of instrumental data (Moberg et
>>> al., 2005), are further desirable when compiling large-scale
>>> reconstructions that seek to yield the true absolute temperature
>>> amplitude. This approach, however, requires a comprehensive
>>> examination of regional proxy data including the seasonality of
>>> temperature signals, and a selection of only those records that
>>> effectively capture low-frequency climate variation. Inclusion of
>>> regional tree ring records in which long-term trends are not
>>> preserved, should be avoided in efforts to reconstruct low frequency
>>> temperature variations (Esper et al., 2004; Melvin, 2004). In these
>>> data, such limitations primarily occur when age-related biases from
>>> tree-ring series are individually estimated and removed ('the
>>> segment length curse' Cook et al., 1995). Similar considerations
>>> apply to documentary evidence, long isotope records and other proxy
>>> sources that should, on a site-by-site basis, be examined for
>>> potential low-frequency limitations.
>>>

>>> The instrumental target data chosen (Esper et al., 2005), and
>>> adjustments made to these data are also vital to the reconstructed
>>> amplitude. A recent analysis of a carefully homogenised instrumental
>>> network from the Alps and surrounding areas (Böhm et al., 2001), for
>>> example, shows the annual temperature trend over the last ca 110
>>> years to be 1.1 °C-twice that observed over the same alpine
>>> gridboxes in the global dataset provided by the Climatic Research
>>> Unit (Jones et al., 1999). Such changes in the character of
>>> observational data, resulting from homogeneity adjustments and
>>> methodology differences (Moberg et al., 2003), directly affect the
>>> temperature amplitude in proxy-based reconstructions, since
>>> instrumental calibration sets the pulse in these paleorecords

Phil,

Why is there so much missing data for the South Pole? The period Jan 75 thru Dec 90 is all missing except Dec 81, July & Dec 85, Apr 87, Apr & Sept 88, Apr 89. Also, from and including Aug 2003 is missing.

Also -- more seriously but correctable. The S Pole is just represented by a single box at 87.5S (N Pole ditto I suspect). This screws up area averaging. It would be better to put the S Pole value in ALL boxes at 87.5S.

I have had to do this in my code -- but you really should fix the 'raw' gridded data.

For area averages, the difference is between having the S Pole represent the whole region south of 85S, and having (as now) it represent one 72nd of this region. It is pretty obvious to me what is better.

This affects the impression of missing data too of course.

Tom.

Cc: "Ben Santer" <santer1@llnl.gov>

Dear all,

attached is a plot of the monthly anomalies from the only box with non-missing data in the bottom row of Phil's grid (centred at 87.5 S). This is from HadCRUT2v that I picked up from the CRU data store in June this year.

Clearly the dates Tom listed are missing in my version too. Furthermore, the values from 1971-1975 are abnormal. They are not all identical, but are all near zero. Perhaps multiplied by 0.1?

Similar problems are apparent in HadCRUT and CRUTEM2v too.

But CRUTEM2 has no gaps and no abnormal periods at the South Pole, so perhaps CRUTEM2 is fine? Tom - if it's urgent, you could extract the South Pole time series from CRUTEM2 and use it to overwrite the other 3 data sets until Phil corrects them.

Regarding the weighting issue...

Given that the grid doesn't have equal-area boxes, there are always going to be compromises with weighting. Even if you do something to sort out the problem at the S. Pole, how about the isolated boxes around the coast of Antarctica, which will be given much less weight than an isolated box in the tropics which might also have only 1 station in. This is partly reasonable because of differences in spatial correlation of temperatures between tropics and high latitudes, but I'm sure that they don't compensate exactly.

Specifically for the poles...

Putting the temperature data into a single box will clearly underweight its contribution in area averages (is it significant from a practical point of view once you get to hemispheric or global scales though?).

Replicating it into all boxes in the bottom row will, on the other hand, gives it too much weight. If the area weighting is calculated simply as $\cos(\text{latitude})$ then the South Pole data will be given this weighting:

$$72 * \cos(87.5) = 3.14$$

whereas one box on the equator (or just off) will be given this weighting:

$$1 * \cos(2.5) = 1.00$$

so, if replicated around all boxes at 87.5 S, the South Pole would have three times the weight of a single tropical box (compared with 23 times less weight if South Pole data appears in only one box).

Perhaps put it in every fourth box, giving a weighting of 0.79 (bit less than tropical, which is reasonable for spatial correlation reasons)?

Cheers

Tim

Tom,

In NZ at the IPCC meeting. Will be here until Dec 17. When I get back I'm off to Switzerland for Christmas on Dec 21.

The South Pole shouldn't be missing. I have all the data for Amundsen-Scott from 1957. I put the data in at one 5 degree grid box, so it doesn't get overweighted.

The South Pole should be at the last grid box (2592) in the 72 by 36 array. Putting the data in all 87.5-90S boxes would overweight the S.Pole stations.

There isn't any data at the N. Pole.

Maybe Tim could check on the missing S.Pole data. I reckon it should be there in all the datasets CRUTEM2 and HadCRUT2 and the v versions.

Cheers

Dear Jen,

There seems to be a problem with the South Pole box (#2592). The data are in CRUTEM2(v) but not in HadCRUT2(v). See the plot and email from Tim Osborn.

Email Tim if you can find what is up. The boxes in the two datasets should be the same.

I'm in NZ at IPCC.

Cheers
Phil

Phil,

Before you finalize anything, please let me get back to you with some additional thoughts. There are some wrinkles that you and Tim don't seem to have thought of.

Tom.

Tom

One further thing (possibly one of the extra wrinkles?) is that while you could put the S Pole data from CRUTEM2 (where it seems correct) into HadCRUT2, it isn't quite correct to put it (as I wrongly suggested) into CRUTEM2v and HadCRUT2v because those should have their high frequency deviations scaled to remove sample-size-related biases. Only a minor difference.

Subject: more on TS feedback

Date: Sun, 18 Dec 2005 13:53:11 -0700

<x-flowed>

Dear Keith, Bette and Eystein:

This email should be read after the one to the entire team - it provides post LA3/TS feedback on figures. Since Bette is going on a short vacation, she and I emailed about her new LIG fig before I left, so she's ready to go when she gets home.

Keith (and Tim), on the other hand, have lots to consider, and I just wanted to reiterate to you (and Bette) that it's a priority for me and Eystein to help you brainstorm all these figures. Here are a few more comments I got on Keith/Tim Figs:

For 6.8:

1) removing the oldest portion of the records from the plot is only ok IF:
-we can justify on an obvious and objective basis - for example that sample depth hits goes down significantly at ca. 700AD or wherever we want to chop it.
-We don't remove part of the series that will give rise to accusations of bias
Thus, it might be better to leave as was in the FOD, just to be safe, or to try multiple versions.

2) had a long talk with Martin Manning about the idea of multiple plots, vs just the existing one (by the way, the TS team WANTS the instrumental part of the fig as we agreed to modify in Chap 6 sessions). I think the best idea is to keep the bottom panel as is, with modifications
- keep the error bars as is
- try a version with some sort of annually-resolved volc forcing placed at the top of the panel, with eruption (sufate) lines sticking down farther for big eruptions
- try inserting some representation of average (median? or?) sample depth along the bottom (time) side of the panel. This will thus show, lots of sample depth back to ca. 1700, then less and less (in steps?). Martin suggests we go one step farther and color the sample depth part of the plot with different colors, based on our expert judgement of confidence. We could have two or three colors - one color for the interval overwhich we have "very likely" confidence (e.g., in the exec summary) and another for just "very." perhaps we want a third for some term reflecting "don't trust inferences regarding hemispheric temp that much over this interval" - this will obviously take some thinking/creativity, but this fig will go all the way to the TSM, so it's worth the effort.

3) linear axis for sure

4) if would still be good to try a density shaded version of this

plot (instead of all the recon lines) for the TS and SPM. When in doubt, make an extra version. We can then share with our team and with Susan.

Thanks for doing this!

Also, FYI, Gabe indicated that her regional plots were not scaled separately. Surprising, but maybe the models are actually better than we thought.

Best, Peck

Hello,

Some dates for your new year diary...

Futerra are launching a series of masterclasses on communicating sustainable development in early 2006.

Communicating Climate Change on a Local and Regional Level

12.30 - 5.30pm

Thursday 26 January 2006

Communicating Sustainable Development

12.30 - 5.30pm

Thursday 23 February 2006

Communicating Climate Change

12.30 - 5.30pm

Thursday 30 March 2006

Using international case studies and proven communication tools, each session is designed to build your confidence to plan and implement campaigns.

"Enthusiastic and friendly trainers with a tremendous amount of knowledge" - Past participant

For more information or to book then please see the attached flyer or visit our [1]website.
The groups will be kept to only 15 people, so please sign up early to avoid disappointment.

The Futerra team wish you a very merry Christmas!

<x-flowed>

Hi Stefan and team - great. David Rind is getting the solar forcing series de jour (latest Lean). I expect Keith back on line soon, and then he can help us figure out what type of simulation(s) we'd like, and what other forcings we ought to use. My take is that it would be good to use the same forcing used in the runs currently in Fig 6.10 (or at least the "best" of those runs - subjective, I'm sure, and all with the old larger amplitude Lean solar), but with the new reduced amplitude forcing.

Fig 6.10 currently has the Bauer et al, 2003 run w/ CLIMBER - is it CLIMBER2? Could/should we just re-run with the new solar in place of the old solar (I don't have the paper here - was the solar used scaled to Lean?).

I'll cc this to the entire team, as there might be other ideas on how to do this - I think we would want two simulations over the last 400 years. One w/ the old Lean solar, one with the new. If we could use one of the existing plotted runs as the "old Lean" run, then we only need one new run. The idea is to show what difference TAR solar (old Lean) vs. AR4 solar (new Lean) means.

So, lets see what Keith and others say, and then line things up to get the run done. If we can do it w/ CLIMBER, great. If we need to involve another EMIC (assuming we're not going to get a AOGCM run done in less than a month), then we need to line that up. Whatever model we use, it should be one already in use by the AR4, so we don't have to worry about the results being published - just the model. Make sense?

Thanks again for the quick reply. Best, Peck

Happy New Year Stefan and Fortunat - just wanted to check in to see where things stand with the EMIC runs you were going to do for the revised Fig 6.10 - that is, with the new Lean solar forcing, and (where the published runs don't already exist) with the old Lean forcing. Again, the purpose of all this is to assess what difference the new solar forcing makes.

Eystein and I are hoping that you've figured out the best experimental framework - e.g., what other forcing series to use. It would be great if you used the same volcanic and trace gas series, if that is possible. I'm cc'ing this to Keith in the hope that he can help us make sure we're making the right decisions.

Also, since Keith is going to be making the new figure comparing the range of obs climate over the last 1000 years to the range of simulated climate over the last 1000 years (i.e., like the fig we showed in our second/Thursday plenary talk), it would be worth thinking if there is any way to scale the solar forcing over the entire last 1000 years to Judith's new reduced-amplitude solar forcing. I'm not sure this is straightforward or not, but if it was possible, we'd have your new runs for inclusion in the new obs vs. simulated climate fig too - this would be helpful.

In any case, the purpose of this email is just to see where we stand, and help keep things moving.

Thanks, Peck

Hi Fortunat et al - glad you have the forcing and can get it out to Anders/Stefan et al. Please do so with recommendations (perhaps building on mine, but suggest what you think is best) for experimental setup - what complete set of forcings should be used, etc.

Please note that we'd like (can we get from both of your groups??) simulated climate to present in two forms: 1) with natural (Lean solar plus volc) plus anthropogenic forcing and 2) with natural only also. It would be good if the results from your runs (Swiss and German) were directly comparable with each other.

Also, please note that I'm waiting for everyone to return to the TSU and let us know the official schedule for the next couple months. There is a finite chance that we'll need your runs, and the figures (which Keith and Tim Osborn will be drafting) well BEFORE the end of January. The reason for this is that this material will be used in the next draft of the TS/SPM (and will need iteration), and we are also likely to be under pressure to have all our figures out for broader WG1 review in January. So, we hope you can speed things up to be run sooner in Jan. OK?

I tried to attach the Christchurch Chap 6 plenary talk, but my phone line is not allowing it today. Will send soon. The figure that is being considered (wanted, might be the better word) for the TS is the one on the upper right of page 7 of the pdf I will send.

Please keep me, Eystein, and Keith in the loop as things develop. It would be great to know what your planned completion date is once you have things running (hopefully soon, pretty please... - we can't afford to be late with things anymore)

Many thanks! Peck

<x-flowed>

Hi Fortunat and friends - I suggest that we (Fortunat, can you do this?) ask Thomas Stocker since he has lots of experience w/ IPCC and knows what we're trying to do too. Is this ok?

If it's ok (and I'm guessing that it might not be ok to use an unpublished extended solar series, as Fortunat suggest - but it would be more comparable to other results in the same figure (our old 6.10)), I think scaling to Bard would be better since this is what has been done more in the other simulations published and in the old Fig. 6.10 - am I correct?

If we can't scale Judith's new recon back to 1000, then we'll just have some simulated series back to 1610.

Again, thanks Fortunat for figuring it all out.

best, peck

<x-flowed>

Keith,

Thanx for this. Interesting. However, I do not think your response is very good. Further, there are grammatical and text errors, and (shocking!!) you have spelled McKitrick wrong. This is a sure way to piss them off.

They claim that three cores do not cross-date for TRW. They also say (without results) that the same applies to MXD (these results may be in their Supp. Mat. -- I presume you checked this).

So, all you need say is ...

- (1) TRW was not the only data used for cross-dating.
- (2) When MXD is used there are clear t-value peaks, contrary to their claim. You can show your Fig. 4 to prove this.
- (3) The 3-core-composite cross-dates with other (well-dated) chronologies (Yamal and Polurula), confirming the MXD-based dating. You can show your Fig. 5 to prove this.

You could say all this in very few words -- not many more than I have used above. As it is, your verbosity will leave any reader lost.

There are some problems still. I note that 1032 is not cold in Yamal. Seems odd. Is it cold in **all** of the three chronologies at issue? Or did a reindeer crap next to one of the trees?

Also, there seems to be a one-year offset in the 1020s in your Fig. 6.

I hope this is useful. I really think you have to do (and can do) a better job in combatting the two Ms. If this stuff gets into Nature, you still have a chance to improve it. Personally, I think it would

be good for it to appear since, with an improved response, you can make MM look like ignorant idiots.

Tom.

From: Keith Briffa <k.briffa@uea.ac.uk>

To: Valerie.Masson@cea.fr,Eystein.Jansen@geo.uib.no, "Eric W Wolff" <EWWO@bas.ac.uk>

Subject: Urgent request for reference letter

Date: Fri Jan 13 15:38:01 2006

Dear Valerie, Eystein and Eric,

We (that is Phil and myself - and of course also Bo) are hoping that you can help us greatly with an application Bo Vinther is submitting to the EU for a Marie Curie Intra-European Fellowship (EIF) , specifically to spend time with Phil and I at CRU working on the dating and interpretation of seasonally-resolved ice core data and tree-ring data.

We are allowed to submit up to 3 reviews or testimonials (though these must be submitted directly through the We would be really grateful if each of you would agree to provide one of these. Unfortunately, if you can make the time to help, these must in submitted by next Thursday.

Please accept our apologies for the lateness of this request - but you can probably understand that , as usual things have had to be cut fine.

The first stage of evaluation is based only on the quality of the applicant (70%) and the quality of the proposed research plan (30%). If the proposal gets through to the second evaluation stage , then other factors such as the quality of the hosts and host institution become relevant .

At this stage we would ask that you read the attached Science Plan and details of the Quality of the Candidate, and write an assessment based primarily on these. We will send precise details of how to submit them early next week. You probably also know just how strong the competition is these days for such awards , so reviews have to be particularly glowing, but it is only because Phil and I are so keen to work with Bo that we are taking the liberty of asking for your support. I am sure you know , and certainly Valerie has indicated to me, how impressive Bo's work is. I am sure he is the sort of person for whom these awards are meant, as he is someone who will be doing important work to advance the field one day.

I am attaching (virtually final) drafts of the relevant sections , which are all that you need to be able to write these testimonials. We will send the full applications when they are complete. It would also help if you stressed your own distinguished qualifications , that make you so well qualified to offer this review. Please let me know whether you are able to do this for us.

Thank you lots
Keith and Phil

Thanks Fortunat. I got the sense from Susan that she'd love to see good old raw ice core data, but I think it makes more sense for Tim and Keith to use what you've sent. It is based on multiple ice cores, and it provides some consistence with our modeling figs.

Tim and Keith - how are you doing? Let me know if you want to discuss figs you're working on beyond what I suggested in my December emails. I appreciate your dealing with the heavy load!

best, peck

Hi all - I'm betting that "provisional acceptance" is not good enough for inclusion in the Second Order draft, but based on what Gene has said, he should have formal acceptance soon - we really need that. Can you give us a read on when you'll have it Gene? Best make this a top priority, or we'll have to leave your important work out of the chapter. Many thanks!!
Peck

Hi Peck, I assume a provisional acceptance is OK by IPCC rules? The timing of these matters are being followed closely by McIntyre (see: <http://www.climateaudit.org/?p=503>) and we cannot afford to be caught doing anything that is not within the regulations. Thus need to consult with martin and Susan on this (see also last mail from Melinda).

Cheers,

Eystein

Thanks Gene - it is worth all the effort, and please keep us (especially Keith) posted on the updates.

best, peck

Thread-Topic: Wahl-Ammann paper on MBH-MM issues
Thread-Index: AcWBF2jTf69xJLFkThuHZzU6qK8tMx+kOAJUB28NG2A=

From: "Wahl, Eugene R" <wahle@alfred.edu>
To: "Jonathan Overpeck" <jto@u.arizona.edu>

Hello Jonathan and Keith:

I'm not sure that I ever sent you the updated Wahl-Ammann paper that was the basis for Steve's provisional acceptance. Here it is. As is, it contains a long appendix (# 1)

on issues with interannual statistics of merit for validation, which was not in the version I had sent you earlier in the year. All the main results and conclusions are the same.

Caspar and I are also now responding to Steve's final requests, based on independent re-review. This is primarily to address publishing Pearson's r^2 and CE calculations for verification, which Steve and the reviewer reason should be done to get the conversation off the topic of us choosing not to report these measures, and onto the science itself. We explain thoroughly in the appendix I mention above why we feel these (and other interannual-only) measures of merit are not of much use for verification in the MBH context, so that the fact we are reporting them is contextualized appropriately. IN FACT, we will be going farther than that and will be bringing this material currently in an appendix into the main text, based on the reasoning below (quoted from another message)

Caspar mentioned yesterday that he talked with Susan Solomon about this paper, and she did not see the appendix we had added concerning the issues about Pearson's r^2 etc. Based on this she therefore thought our text was weak in this area in relation to McIntyre's criticisms. Caspar thought, and I agree, that we need to bring this stuff OUT of the appendix and get it INTO the methods section, so that it won't be so easily missed!! We are working on this--which will include other material as well in the text proper.

Also, we are going ahead with an even further-expanded discussion on the issues with r^2 , which itself will probably become an appendix in the final text (it had been slated for publication as supplemental web-site material). This expanded discussion will go into additional reasoning (with graphics) concerning the basis for r^2 not being useful in this context. It will give a vector space analysis of the issues, and explicit visual demonstration of how these issues with r^2 play out in terms of false negative and false positive errors in validation.

Let me know if I can be of any further help in all this. Apologies if this message seems long. I did my best to keep it short, but I'm a bit tired and it is hard to edit well in that state!

Peace, Gene

Subject: RE: Wahl-Ammann paper on MBH-MM issues

Hello Jonathan:

1) I want you to know that we heard from Steve Schneider today that our paper with Climatic Change has been provisionally accepted for publication. The provisions Steve outlined are ones we fully accept and will implement (extra statistics of merit and remaking of graphics), so this paper can be viewed as accepted, I should think.

Caspar and I are getting right on it. We wanted you to know this ASAP.

2) The Ammann-Wahl GRL comment on the MM GRL paper from early 2005 is being sent for final review along with a response by MM that GRL is soliciting. We had thought, based on info from James Famiglietti (editor), that this article had been accepted and the response from MM was just being sought. We did not realize that the entire package of comment and response would be put through a final review. We just heard about this last Friday. Sorry that we had that one mistaken.

Hope you are well. Best wishes on IPCC work.

Peace, Gene

<x-flowed>
Dear all,

Please find attached the Bern2.5CC model output for the IPCC-AR4 millennium simulations, all spanning the period from 1000 - 1998AD. Some plots including a preliminary comparison between CLIMBER-2 and Bern2.5CC results are additionally included (see infos below).

1. The following Bern2.5CC files are attached (with the simulation tag as specified in Fortunat's readme document):

Simulation B1.1: Bern2.5CC_bard08_volcCrow_CO2_nonCO2_1000-1998_ar4.dat
Simulation B1.2: Bern2.5CC_bard25_volcCrow_CO2_nonCO2_1000-1998_ar4.dat
Simulation B2 : Bern2.5CC_WLS-2005_volcCrow_CO2_nonCO2_1000-1998_ar4.dat
Simulation B3.1: Bern2.5CC_bard08_volcCrow_CO2_anthr0_1000-1998_ar4.dat
Simulation B3.2: Bern2.5CC_bard25_volcCrow_CO2_anthr0_1000-1998_ar4.dat
Simulation B3.3: Bern2.5CC_WLS-2005_volcCrow_CO2_anthr0_1000-1998_ar4.dat
Simulation B4 : Bern2.5CC_ctrl_1000-1998_ar4.dat

The variables stored are: year AD, globally averaged surface air temperature, and northern hemispheric and southern hemispheric surface air temperature. The most important information about model setup and references is included in the extended header in each file. Please note that the information on the forcing timeseries applied are specified in the filename only!

Please let me know if something is unclear or if you want additional informations about these simulations in particular or the Bern2.5CC model in general. I can also provide more output variables if desired (such as e.g. MOC, Sea level, ...).

2. In addition, the following plots with CLIMBER-2 and Bern2.5CC results are attached:

Dgmairtnorm_millennium_Bern2.5CC-CLIMBER2_1000_1998_ipccar4.eps
Dgmairtnorm_millennium_Bern2.5CC-CLIMBER2_offset0.8_1000_1998_ipccar4.eps
Dgmairtnorm_millennium_Bern2.5CC_1000_1998_ipccar4.eps
Dgmairtnorm_millennium_CLIMBER2_1000_1998_ipccar4.eps

All these plots show the anomaly in global mean surface air temperature

with respect to the value in year 1001AD from either CLIMBER-2, Bern2.5CC, or both. Let me know if you have questions or comments about the plots.

With best regards,

Gian-Kasper

# Some model setup informations:
# -----
# All runs with horizontal/vertical diffusion
#
# Run with standard ocean parameters
# as used in Plattner et al. 2001/2002
```

```
#       with Kv (diffusivity) 4*10^-5 m2/s
#
# Climate sens. set to ~ 3.2 degrees C
# parameterized see Knutti et al. (Clim. Dyn. 2003)
#
# Model version is annual mean.
#
# No radiation code, CO2 radiative forcing calculated
# for as RF=5.35*ln(CO2/CO2_preind),
# Non-co2 radiative forcing prescribed according to
# Joos et al. GBC 2001 with updates for solar forcing
#
# More model description:
# -----
# Zonally averaged dynamical ocean with 3 basins and
# Southern Ocean, zonally averaged one layer energy
# and moisture balance atmosphere, thermodynamic
# sea ice (Stocker et al., J. Climate 1992).
#
# Carbon cycle components: Ocean/Atm/Terr.biosphere;
# Ocean carbon cycle is a description of the cycles
# of organic carbon and CaCO3 (Marchal et al., Tellus
# Tellus B), based on Redfield approach using PO4 as
# biolimiting nutrient.
#
# Land Biota: Lund-Jena-Postdam Dynamical Global
#               Vegetation Model (LPJ-DGVM)
# at GCM resolution (Gerber et al. 2003, Climate
# Dynamics; Sitch et al. 2003, Global Change Biology)
#
# LPJ forced by Cramer/Leemans annual mean
# climatology plus interannual climate variability
# from Hadley simulation (30-recycled climate) plus
# changes in the fields of surface temperature,
# precipitation, and cloudcover as simulated with the
# Impulse-EOF version of ECHAM-3/LSG in response to
# projected radiative forcing changes.
#
# Land use changes are not explicitly considered.
#
# Impact of climate change on terrestrial C-storage
# included

# IPCC AR4 Millenium Runs output (vary solar forcing)
# ++++++
#
# Model: Bern2.5CC version with active C-cycle
# -----
# Prescribed forcing timeseries as described in file
# readme_doRuns_IPCC_Chap6_millennium_21jan06.txt
# provided by F. Joos, University of Bern.

#
# Some model setup informations:
# -----
# All runs with horizontal/vertical diffusion
#
# Run with standard ocean parameters
#   as used in Plattner et al. 2001/2002
#   with Kv (diffusivity)  $4 \cdot 10^{-5}$  m2/s
#
# Climate sens. set to ~ 3.2 degrees C
# parameterized see Knutti et al. (Clim. Dyn. 2003)
#
# Model version is annual mean.
#
# No radiation code, CO2 radiative forcing calculated
# for as  $RF = 5.35 \cdot \ln(CO2/CO2\_preind)$ ,
# Non-co2 radiative forcing prescribed according to
# Joos et al. GBC 2001 with updates for solar forcing
#
# More model description:
# -----
# Zonally averaged dynamical ocean with 3 basins and
# Southern Ocean, zonally averaged one layer energy
# and moisture balance atmosphere, thermodynamic
# sea ice (Stocker et al., J. Climate 1992).
#
# Carbon cycle components: Ocean/Atm/Terr.biosphere;
# Ocean carbon cycle is a description of the cycles
# of organic carbon and CaCO3 (Marchal et al., Tellus
# Tellus B), based on Redfield approach using PO4 as
# biolimiting nutrient.
#
# Land Biota: Lund-Jena-Postdam Dynamical Global
#               Vegetation Model (LPJ-DGVM)
# at GCM resolution (Gerber et al. 2003, Climate
# Dynamics; Sitch et al. 2003, Global Change Biology)
#
# LPJ forced by Cramer/Leemans annual mean
# climatology plus interannual climate variability
# from Hadley simulation (30-recycled climate) plus
# changes in the fields of surface temperature,
# precipitation, and cloudcover as simulated with the
# Impulse-EOF version of ECHAM-3/LSG in response to
# projected radiative forcing changes.
#
# Land use changes are not explicitly considered.
#
# Impact of climate change on terrestrial C-storage
# included
#

# IPCC AR4 Millenium Runs output (vary solar forcing)
# ++++++
#
# Model: Bern2.5CC version with active C-cycle
# -----
# Prescribed forcing timeseries as described in file
```

```
# readme_doRuns_IPCC_Chap6_millennium_21jan06.txt
# provided by F. Joos, University of Bern.

#
# Some model setup informations:
# -----
# All runs with horizontal/vertical diffusion
#
# Run with standard ocean parameters
#   as used in Plattner et al. 2001/2002
#   with Kv (diffusivity)  $4 \cdot 10^{-5}$  m2/s
#
# Climate sens. set to ~ 3.2 degrees C
# parameterized see Knutti et al. (Clim. Dyn. 2003)
#
# Model version is annual mean.
#
# No radiation code, CO2 radiative forcing calculated
# for as  $RF=5.35 \cdot \ln(CO2/CO2\_preind)$ ,
# Non-co2 radiative forcing prescribed according to
# Joos et al. GBC 2001 with updates for solar forcing
#
# More model description:
# -----
# Zonally averaged dynamical ocean with 3 basins and
# Southern Ocean, zonally averaged one layer energy
# and moisture balance atmosphere, thermodynamic
# sea ice (Stocker et al., J. Climate 1992).
#
# Carbon cycle components: Ocean/Atm/Terr.biosphere;
# Ocean carbon cycle is a description of the cycles
# of organic carbon and CaCO3 (Marchal et al., Tellus
# Tellus B), based on Redfield approach using PO4 as
# biolimiting nutrient.
#
# Land Biota: Lund-Jena-Postdam Dynamical Global
# Vegetation Model (LPJ-DGVM)
# at GCM resolution (Gerber et al. 2003, Climate
# Dynamics; Sitch et al. 2003, Global Change Biology)
#
# LPJ forced by Cramer/Leemans annual mean
# climatology plus interannual climate variability
# from Hadley simulation (30-recycled climate) plus
# changes in the fields of surface temperature,
```

```

# precipitation, and cloudcover as simulated with the
# Impulse-EOF version of ECHAM-3/LSG in response to
# projected radiative forcing changes.
#
# Land use changes are not explicitly considered.
#
# Impact of climate change on terrestrial C-storage
# included
#

# IPCC AR4 Millenium Runs output (vary solar forcing)
# ++++++
#
# Model: Bern2.5CC version with active C-cycle
# -----
# Prescribed forcing timeseries as described in file
# readme_doRuns_IPCC_Chap6_millennium_21jan06.txt
# provided by F. Joos, University of Bern.
#

#
# Some model setup informations:
# -----
# All runs with horizontal/vertical diffusion
#
# Run with standard ocean parameters
#   as used in Plattner et al. 2001/2002
#   with Kv (diffusivity) 4*10^-5 m2/s
#
# Climate sens. set to ~ 3.2 degrees C
# parameterized see Knutti et al. (Clim. Dyn. 2003)
#
# Model version is annual mean.
#
# No radiation code, CO2 radiative forcing calculated
# for as RF=5.35*ln(CO2/CO2_preind),
# Non-co2 radiative forcing prescribed according to
# Joos et al. GBC 2001 with updates for solar forcing
#
# More model description:
# -----
# Zonally averaged dynamical ocean with 3 basins and
# Southern Ocean, zonally averaged one layer energy
# and moisture balance atmosphere, thermodynamic
# sea ice (Stocker et al., J. Climate 1992).
#
# Carbon cycle components: Ocean/Atm/Terr.biosphere;
# Ocean carbon cycle is a description of the cycles
# of organic carbon and CaCO3 (Marchal et al., Tellus
# Tellus B), based on Redfield approach using PO4 as
# biolimiting nutrient.
```

```

#
# Land Biota: Lund-Jena-Postdam Dynamical Global
#           Vegetation Model (LPJ-DGVM)
# at GCM resolution (Gerber et al. 2003, Climate
# Dynamics; Sitch et al. 2003, Global Change Biology)
#
# LPJ forced by Cramer/Leemans annual mean
# climatology plus interannual climate variability
# from Hadley simulation (30-recycled climate) plus
# changes in the fields of surface temperature,
# precipitation, and cloudcover as simulated with the
# Impulse-EOF version of ECHAM-3/LSG in response to
# projected radiative forcing changes.
#
# Land use changes are not explicitly considered.
#
# Impact of climate change on terrestrial C-storage
# included
#

# IPCC AR4 Millenium Runs output (vary solar forcing)
# ++++++
#
# Model: Bern2.5CC version with active C-cycle
# -----
# Prescribed forcing timeseries as described in file
# readme_doRuns_IPCC_Chap6_millennium_21jan06.txt
# provided by F. Joos, University of Bern.
#

#
# Some model setup informations:
# -----
# All runs with horizontal/vertical diffusion
#
# Run with standard ocean parameters
#   as used in Plattner et al. 2001/2002
#   with Kv (diffusivity) 4*10^-5 m2/s
#
# Climate sens. set to ~ 3.2 degrees C
# parameterized see Knutti et al. (Clim. Dyn. 2003)
#
# Model version is annual mean.
#
# No radiation code, CO2 radiative forcing calculated
# for as RF=5.35*ln(CO2/CO2_preind),
# Non-co2 radiative forcing prescribed according to
# Joos et al. GBC 2001 with updates for solar forcing
#
# More model description:
# -----
```

```

# Zonally averaged dynamical ocean with 3 basins and
# Southern Ocean, zonally averaged one layer energy
# and moisture balance atmosphere, thermodynamic
# sea ice (Stocker et al., J. Climate 1992).
#
# Carbon cycle components: Ocean/Atm/Terr.biosphere;
# Ocean carbon cycle is a description of the cycles
# of organic carbon and CaCO3 (Marchal et al., Tellus
# Tellus B), based on Redfield approach using PO4 as
# biolimiting nutrient.
#
# Land Biota: Lund-Jena-Postdam Dynamical Global
#           Vegetation Model (LPJ-DGVM)
# at GCM resolution (Gerber et al. 2003, Climate
# Dynamics; Sitch et al. 2003, Global Change Biology)
#
# LPJ forced by Cramer/Leemans annual mean
# climatology plus interannual climate variability
# from Hadley simulation (30-recycled climate) plus
# changes in the fields of surface temperature,
# precipitation, and cloudcover as simulated with the
# Impulse-EOF version of ECHAM-3/LSG in response to
# projected radiative forcing changes.
#
# Land use changes are not explicitly considered.
#
# Impact of climate change on terrestrial C-storage
# included
#

# IPCC AR4 Millenium Runs output (vary solar forcing)
# ++++++
#
# Model: Bern2.5CC version with active C-cycle
# -----
# Prescribed forcing timeseries as described in file
# readme_doRuns_IPCC_Chap6_millennium_21jan06.txt
# provided by F. Joos, University of Bern.
#

# fax: ++41 (0)31 631-87-42
#
# Some model setup informations:
# -----
# All runs with horizontal/vertical diffusion
#
# Run with standard ocean parameters
#   as used in Plattner et al. 2001/2002
#   with Kv (diffusivity) 4*10^-5 m2/s
#
# Climate sens. set to ~ 3.2 degrees C
# parameterized see Knutti et al. (Clim. Dyn. 2003)
```

```
#
# Model version is annual mean.
#
# No radiation code, CO2 radiative forcing calculated
# for as  $RF=5.35*\ln(CO2/CO2\_preind)$ ,
# Non-co2 radiative forcing prescribed according to
# Joos et al. GBC 2001 with updates for solar forcing
#
# More model description:
# -----
# Zonally averaged dynamical ocean with 3 basins and
# Southern Ocean, zonally averaged one layer energy
# and moisture balance atmosphere, thermodynamic
# sea ice (Stocker et al., J. Climate 1992).
#
# Carbon cycle components: Ocean/Atm/Terr.biosphere;
# Ocean carbon cycle is a description of the cycles
# of organic carbon and CaCO3 (Marchal et al., Tellus
# Tellus B), based on Redfield approach using PO4 as
# biolimiting nutrient.
#
# Land Biota: Lund-Jena-Postdam Dynamical Global
#               Vegetation Model (LPJ-DGVM)
# at GCM resolution (Gerber et al. 2003, Climate
# Dynamics; Sitch et al. 2003, Global Change Biology)
#
# LPJ forced by Cramer/Leemans annual mean
# climatology plus interannual climate variability
# from Hadley simulation (30-recycled climate) plus
# changes in the fields of surface temperature,
# precipitation, and cloudcover as simulated with the
# Impulse-EOF version of ECHAM-3/LSG in response to
# projected radiative forcing changes.
#
# Land use changes are not explicitly considered.
#
# Impact of climate change on terrestrial C-storage
# included
#
