Dear Keith, March 6, 1996

I and Eugene received your E-mail of 04.03.1996. This day I talked over the telephone with Eugene and he asked me to send an answer from both of us.

Thank you for the information concerning proposals to the INCO/COPERNICUS. We agree with your strategy used and we hope that this proposal will not be rejected.

The results of INTAS-RFBR proposal will be known at the beginning of May. We know that they received many proposals and a competition is high (only 1 in 10 proposals might get money). Of course, you included in as a participant. Fritz is a coordinator from the INTAS countries.

This year our laboratory received two small grants (approximately 8,000-10,000 USD per year) from the Russian Foundation of Basic Researches (RFBR) for the next three years: the first one for developing the Yamal supra-long chronology and the second one for developing tree-ring chronologies from living trees growing at the polar timberline in Siberia (together with Vaganov's laboratory). These money are very important for us as they will allow to maintain the staff of our laboratories.

I and Valery Mazepa were in Krasnoyarsk during one month and together with E.Vaganov wrote the manuscript of book "Dendroclimatic Studies in the Ural-Siberian Subarctic". The problem now is to find money for its publication. If we find enough money soon (20 million roubles), the book will be published this autumn. We analysed 61 mean ring-width and 6 cell chronologies which we intend to publish in form of tables in the Appendix. We can send to you all raw measurements which were used for developing these chronologies.

Of course, we are in need of additional money, especially for collecting wood samples at high latitudes and in remote regions. The cost of field works in these areas is increased many times during the last some years. That is why it is important for us to get money from additional sources, in particular from the ADVANCE and INTAS ones. Also, it is important for us if you can transfer the ADVANCE money on the personal accounts which we gave you earlier

and the sum for one occasion transfer (for example, during one day) will not be more than 10,000 USD. Only in this case we can avoid big taxes and use money for our work as much as possible. Please, inform us what kind of documents and financial reports we must represent you and your administration for these money.

I and Eugene have a possibility to participate in the Cambridge meeteng in July, but we need extra many and special invitations. If you do not have enough money to invite both of us, Eugene does not insist upon this visit.

The best wishes to you and Phil.

Yours sincerely

Stepan Shiyatov

Dear Keith,

I have bought the tickets from Moscow to London and back. My arrival to London (Heathrow Airport) is by flight SU 245 (Aeroflot Company) on July 19. Departure from Moscow is at 20.10 (local time), arrival to London is approximately at the same local time. As I know, Evgeny Vaganov did not buy tickets until now, but he informed of my dates and can buy tickets the same flights. My departure from London to Moscow is on August 1 by the Aeroflot Company flight SU 244 at 09.00 of local time.

Please, inform me how can I arrive at Cambridge from London? Is there the program of this meeting? We must be ready to do some reports? For example, I can prepare a report about the progress in developing the Yamal supra-long chronology and together with Evgeny about dendroclimatic investigation in the Ural-Siberian subarctic.

Rashit Hantemirov and Alexander Surkov will go soon to the Yamal peninsula (June 24). This summer they want to collect subfossil material from areas which are much more remote and situated at higher latitudes. We hoped to use some money of the ADVANCE project. But we have not received this money until now and the program of collecting during this summer will be reduced.

Some days ago I received an information that the INTAS-RFBR project was rejected. The competition was very high.

Sincerely yours

Stepan Shiyatov

Subject: URGENT RESPONSE NEEDED - Early Detection Work
Date: Wed, 26 Jun 1996 16:13 -0700 (PDT)

Dr. Jones,

I am contacting you on behalf of Dave Bader and Tim Barnett regarding a couple action items in support of early detection on climate change. Based upon the anticipated award for NOAA support during fiscal year 1997 on climate change data and detection, DOE has authorized the Pacific Northwest National Laboratory (PNNL) to utilize existing funding through 9/30/96 to conduct a meeting of the experts, and to begin preliminary investigations.

PNNL would like to place a contract with you as soon as possible to provide support through 9/30/96. In order to place a contract with you, I need to submit a statement of work and signed cost proposal to our Contracts Department. If you could please fax this to me as soon as possible on (509) 375-2698, it would be greatly appreciated.

I thought your activity may look something like the following (feel free to change/edit):

Scope of Work

Dr. Phillip Jones shall begin initial work in support of the pilot project identified in the Early Detection of Climate Trends report. He shall prepare for and participate in a meeting on greenhouse signal detection, to be held in Washington, DC on September 17-18, 1996. In addition, Dr. Jones shall conduct a preliminary analysis ?????? (please provide input)

Deliverables

Prepare for and participate in 9/17-18, 1996 meetings on greenhouse signal.

Provide a summary report on the preliminary analysis of ?????? on or before September 30, 1996.

Also, for your information the current plan for the meeting is for September 17-18, 1996 at the Courtyard by Marriott - Greenbelt, 6301 Golden Triangle Drive,

Greenbelt, MD. (301) 441-3311, fax: (301) 441-4978. Government room rate is \$89/day.

When you provide your cost estimate, it would be appreciated if you could provide your hourly rate, in addition to travel estimates for the September meeting. To expedite the process, it is very helpful if can include documentation to support your hourly rate.

Please feel free to contact me with any questions. My phone number is 509-375-2861, fax is 509-375-2698.

Thank you,

Karen

Dear Phil,

It looks like you have found Baitoushan. Vol. 2 lists Kuwae as VEI 6 in 1452 +/- 10 AD. How accurate are your dates? By the way, Chris Newhall thinks 1600 is the Parker volcano on Mindanao in the Philippines. He hasn't published that so far, as I know.

Could you please define "utter prat" for me? Sometimes I think we speak the same language, and sometimes I'm not so sure.

I'm doing fine. We have a new building with nice new offices. I'm going to Australia next week with Sherri and Danny, and after the meeting, will visit Cairns, Adelaide, and New Zealand. I'm looking forward to skiing on a volcano, if it stops erupting.

Subject: Re: Climatic warming in Tasmania

Date: Fri, 09 Aug 1996 20:04:00 +1100

Cc: Ed Cook <drendro@ldgo.columbia.edu>, NNU-NB@palais.natmus.min.dk, k.briffa@uea.ac.uk, Mike Barbetti <mikeb@emu.su.oz.au>, zetterberg@joyl.joensuu.fi, rjf@dar.csiro.au

Dear Neville,

You mentioned to me some time ago that in your view, the 11-year solar cycle did not influence temperature. There have been numerous attempts by academics to establish a correlation, but each has been shot down on some ground or other. I remember Barrie Pittock was especially dismissive of attempts to correlate solar cycle with temperature.

Have you tried this approach?

Load "Mathematica" into your PC and run the following set of instructions -

```
data = ReadList[ "c:\sydney.txt", Number]
dataElements = Length[data]
X = ListPlot[ data, PlotJoined-> True];
fourierTrans = Fourier[data];
ListPlot[Abs[fourierTrans], PlotJoined -> True];

fitfun1 = Fit[data, {1,x,x^2,x^3,Sin[11 2 Pi x/dataElements],
    Cos[11 2 Pi x/dataElements]},x];
fittable = Table[N[fitfun1], {x, dataElements}];
Y = ListPlot[fittable, PlotJoined -> True];
Show[X, Y]
```

The reference to "c:\sydney.txt" is a suggested pathname for the following set of data - which is Sydney's annual mean temperature.

```
16.8 16.5 16.8 17 17 16.7 17.1 17.4 17.9 17.4 17.2 17.1 16.9 17 17.2 17.2 17.4
17.6 17.6 17.6 16.7 17.1 16.8 17.4 16.8 17.3 17.8 17.5 17.1 17.2 17.6 17.3 17.1
16.9 16.9 17.3 17.3 17.3 17.6 17.5 17.4 17.2 17.1 17.3 17.2 17.2 16.9 17.5 17.4
17.2 17 17.5 17.4 17.5 17.7 18.3 17.8 17.4 17.2 17.4 18.3 17.3 18 18.1 18 17.5
17.3 18 17 18.2 17.4 17.6 17.5 17.4 17.1 17.4 17.3 17.5 17.7 18 17.8 18 17.4
17.8 16.8 17.5 17.4 17.6 17.6 17.2 17.4 17.9 17.9 17.6 17.7 17.8 17.7 17.6 17.8
18.3 18 17.6 17.8 17.8 17.8 18.1 17.9 17.5 17.8 18.3 18 17.7 17.3 17.5 18.5 17.4
17.8 17.7 17.8 17.7 18 18.5 18.2 17.8 18.1 17.5 17.8 17.8 18 18.6 18.1 18.1
18.6
```

So Far so good.

"Mathematica" first plots out the data itself (see Attachment 1)

The first part of the instruction set lets "mathematica" do a Fourier Transform on the data, ie. searching out the periodicities, if there are any. The result is shown on Attachment 2.

The transform result shows a sharp spike at the 11 year point (I wonder what is significant about 11 years?). The second part of the instructions now acts upon this observed spike (the Cos 11 bit), to extract it's waveform from the rest of the noise. The result is shown as a waveform in attachment 3, the waves having an 11-year period, with the long-term Sydney warming easily evident.

Attachment 4 shows the original Sydney data overlaid against the 11-year periodicity.

It would appear that the solar cycle does indeed affect temperature.

(I tried the same run on the CRU global temperature set. Even though CRU must be highly smoothed by the time all the averages are worked out, the 11-year pulse is still there, albeit about half the size of Sydneys).

Stay cool.

Dear Doug,

In response to Jay Fein's e-mail re den-cen, here are some points (which may merely echo where you are already).

(1) Why study den-cen? Reason is: improve understanding of climate system to aid in detection and prediction. You should read Ch. 8 (detection) of IPCC WGI SAR in this regard.

(2) How to study den-cen? Models and observed data are equally important. Models (coupled O/AGCMs) can only give the internal component of variability, instrumental and paleodata give internal-plus-external.

(3) How useful are paleodata? I support the continued collection of such data, but I am disturbed by how some people in the paleo community try to oversell their product. A specific example is the ice core isotope record, which correlates very poorly with temperature on the annual to decadal timescale (and possibly also on the century timescale)---question, how do we ever demonstrate the usefulness or otherwise of ice core isotopes on this timescale?

There are other well known proxy data issues that need careful thought...

(a) Sedimentary records---dating. Are ¹⁴C-dated records of any value at all (unless wiggle matched)?

(b) Seasonal specificity---how useful is a proxy record that tells us about a single season (or only part of the year)?

(c) Climate variance explained by the proxy variable--close to zero for ice core isotopes, up to 50% for tree rings, somewhere in between for most other indicators. How valuable are such partially explained records in helping explain the past?

(d) Signal-to-noise problems---a key issue is, what role has external forcing had on climate over the past 10,000 years. There is a tendency to interpret observed changes as evidence of external forcing---usually unjustifiably. Few workers in the area realize that paleo interpretation has a detection aspect, just like interpreting the past 100+ years---only much more difficult. More work is needed on this.

(e) Frequency dependence of explained variance---the classic example here is tree rings, where it is exceedingly difficult to get out a credible low frequency (50+ year time scale) message. Work in this area could reap useful rewards.

(f) Coverage---what about den-cen data from the oceans? We need much more of this, especially in regions that might provide insights into mechanisms (like NADW changes).

(4) Causes. Here, ice cores are more valuable (CO₂, CH₄ and volcanic aerosol changes). But the main external candidate is solar, and more work is required to improve the "paleo" solar forcing record and to understand how the climate system responds both globally and regionally to solar forcing.

I hope these very hasty ramblings are helpful

Cheers,
Tom

Dear Jean-Claude

It is good news indeed that these initiatives are now meaningfully underway to join the palaeo , pure climate , and modelling communities. I will join the short CLIVAR/PAGES meeting (24/25 Oct.) and a colleague - Tim Osborn will attend the larger meeting from Oct.28-Nov.1. As for question about new results , Ed Cook and I have a paper in press describing an initial attempt to reconstruct a North Atlantic Oscillation index back into the 1700s using tree-ring chronologies in Europe and North America. I will have a copy sent to you. Otherwise we have a paper soon to come out in an American book describing our early analyses of the growing Russian data. This work, developing the density network is progressing well and we have some very good reconstructions of growing season degree days- excellent spatial maps over western siberia going back several hundred years. We recently published a paper in Nature describing a 1000-year summer temperature reconstruction in the northern Urals and a brief but interesting paper demonstrating a strong volcanic influence in the tree-ring density data when they show extreme low density over large areas. We have very interesting developments from these areas of work but they are only now being written up.

The usefull thing to stress is that these researches are in progress and the development of the tree-ring network is continuing well and is already providing patterns of past climate variability in northern Europe/Russia and at a number of special locations- nortern Sweden/Finland, Yamal, and Taimyr we have already got continuous 2000-year chronologies and have the potential (indeed we already are) to build 7-8000 year series at ech location.

I will send you some reprints/preprints and an overhead that shows the present state of the northern chronology network. Any stress on the importance of future collaboration btween us and the Russians would be wellcome. I have just heard that a proposal I submitted to Copernicus to do just this was to my amazement ruled not relevant to the programme!

I look forward to seeing you in October. Very best wishes. Needless to say, if I can offer any help with drafting the white paper or similar I am happy to oblige.

cheers

Keith

Subject: Re: russian data
Date: Tue Sep 17 16:42:28 1996

Gary,
it's great to hear from you. The stuff you are doing is very interesting to say the least. From the details you give the precip. stuff looks the more relevant for the Holocene though I note that you don't have a manuscript yet. The other stuff is of course interesting but I would have to see it and the board would want the larger implications of the stats clearly phrased in general and widely understandable (by the ignorant masses) terms before they would consider it not too specialised. I suspect that this might not be straight forward. Are you not being (in the time honoured Don Graybill fashion) too demanding of the response function results when you say deriving a transfer function is not justified? We all strive for perfection but does it exist? Seriously , it would be easier as regards publication policy to get the Editor to accept a reconstruction/reconstruction based paper than one describing chronology inferences.

I don't know whether this is any use but I hope you'll send us something. I also hope life going O.K. for you these days. I can't see me getting to Tucson for some considerable time and I don't suppose you have any plans for cruising this way so I'll see you when I see you.

keep in touch and let me know what you you decide.

the best to you
Keith

Dear Stepan

I have received the receipts. Thankyou.
Unfortunately I have also heard that our request to COPERNICUS was not successful. I am very disappointed about this. The letter I recieved said that the proposal " was not considered relevant" so you can imagine that I am seriously exploring what this is all about. I have just returned from a PEP3 meeting in Paris . I tried to emphasise how important the Russian work is and , of course , our collaboration. I am relly angry that our proposal was not considered by referees - just rejected by the committee.

Thanks for the piece for the Web page - It is already on. It is now more important than ever that we publish some papers over the next few months on the different aspects of the network reconstructions and the long series. Have you considered my suggestion to think about a long,detailed paper on the Yamal work for submission to The Holocene? I am happy to help as much as possible with such an effort. I am glad you are safely home and I send my best wishes to you all.

Keith

Subject: kyrgyzstan and siberian data
Date: Thu, 19 Sep 1996 15:37:09 -0700

Keith,

Thanks for your consideration. Once I get a draft of the central and southern siberian data and talk to Stepan and Eugene I'll send it to you.

I really wish I could be more positive about the Kyrgyzstan material, but I swear I pulled every trick out of my sleeve trying to milk something out of that. It was pretty funny though - I told Malcolm what you said about my possibly being too Graybill-like in evaluating the response functions - he laughed and said that's what he thought at first also. The data's tempting but there's too much variation even within stands. I don't think it'd be productive to try and juggle the chronology statistics any more than I already have - they just are what they are (that does sound Graybillian). I think I'll have to look for an option where I can let this little story go as it is.

Not having seen the sites I can only speculate, but I'd be optimistic if someone could get back there and spend more time collecting samples, particularly at the upper elevations.

Yeah, I doubt I'll be over your way anytime soon. Too bad, I'd like to get together with you and Ed for a beer or two. Probably someday though.

Cheers, Gary

To: k.briffa@uea.ac.uk
Subject: Rashit
Date: Thu, 10 Oct 96 13:24:01 +0500

Dear Keith,
enclosed are data concerning Yamal chronology.
1 - list of samples: 139 subfossil samples (checked only),
covered time span from about 350 BC and 18 samples from living
trees (jah- from Yada river, m- and x- Hadyta river, por- from
Portsa river);
2 - general chronology (1248 BC - 1994 AD). I have some little
doubt about 360 BC - may be it is false. It was found that
in chronology I sent you before 155 BC was false ring;
3 - ring widths of living trees from Yada and Hadyta;
4 - ring widths of living trees from Portsa. Some of them didn't
include in chronology, because were not measured at that time;
5 - ring widths of subfossil trees. Zero means that ring didn't
find on sample.

I don't send description of collection sites, deposits and etc.
for the present. Some details you can find in our article
(Shiyatov,....., Loosli). By the way, do you know something about
its fate?

Please, inform me if you have any questions about these data.

Sincerely yours,
Rashit Hantemirov

Subject: the Yamal data
Date: Wed Oct 30 17:45:53 1996

Dear Rashit,

As always I seem to have been away bullshiting and politiking in various meetings for weeks! I try to convince myself that this is of use to us as a dendrochronological community but I am not so sure how much that is really true these days. I have the data you sent and I had to get someone here to decode it for me . That is fine now so I would like to try and reformat and RCS it . I will be back in touch soon. Your paper is in review for Denrochronologia. I am very keen to get a much more detailed paper in The Holocene dealing with this stuff and I hope you and Stepan will consider this - perhaps for some time in spring next year. Sorry I wasn't in touch sooner. Please give my regards to Stepan and Valerie.

very best wishes

Keith

Subject: the Yamal data
Date: Thu Oct 31 12:01:04 1996

Dear Rashit,

In looking at the data I now see that you have only sent data from abot 350bc onwards. What is the situation with the earlier data. I am very interested in the details of the 1st millennium B.C. and especially this period from about 500 to 100 B.C. We still have a gap in the Tornetrask data at about 350 B.C.

I was of the opinion that this period was very low growth in the chronology of yours shown by Stepan in Cambridge - but it does not seem so low in the chronology he gave me. What are your thoughts on this and is it possible to get the earlier data when you are happy with them?Thanks very best wishes

Keith

Eugene

I have not received my copy of the book. A message to Malcolm is the best idea. I have been experimenting with the Yamal data mostly trying to fit RCS curves - and am finding problems with recent local chronologies behaving oddly - i.e. too much growth in recent years makes it difficult to derive a valid age/growth curve. I have produced a rcs standardised curve for taimyr and will fax a copy to you. I will send comments to you and stepan on the two papers reviewed for dendrocronologia on the development of the yamal and taimyr chronologies. I have made major changes to the tracheid paper and need to type and send the new version to you - also there are problems understanding some bits - I will ask specific questions. How goes the organisation of the Krasnoyarsk meeting? Stepan /Rashit I have had some comments on the Yamal paper that I will try to email tommorow.

best wishes
Keith

Phil

Remember all the fun we had last year over 1995 global temperatures, with early release of information (via Oz), "inventing" the December monthly value, letters to Nature etc etc?

I think we should have a cunning plan about what to do this year, simply to avoid a lot of wasted time.

I have been discussing with David P and suggest the following:

1. By 20 Dec we will have land and sea data up to Nov
2. David (?) computes the December land anomaly based on 500hPa heights up to 20 Dec.
3. We assume that Dec SST anomaly is the same as Nov
4. We can therefore give a good estimate of 1996 global temps by 20 Dec
5. We feed this selectively to Nick Nuttall (who has had this in the past and seems now to expect special treatment) so that he can write an article for the silly season. We could also give this to Neville Nicholls??
6. We explain that data is provisional and how the data has been created so early (ie the estimate for Dec) and also
7. We explain why the globe is 0.23k (or whatever the final figure is) cooler than 95 (NAO reversal, slight La Nina). Also that global annual avg is only accurate to a few hundredths of a degree (we said this last year - can we be more exact, eg PS/MS 0.05K or is this to big??)
8. FROM NOW ON WE ANSWER NO MORE ENQUIRIES ABOUT 1996 GLOBAL TEMPS BUT EXPLAIN THAT IT WILL BE RELEASED IN JANUARY.

9. We release the final estimate on 20 Jan, with a joint UEA/MetO press release. It may not evoke any interest by then.

10. For questions after the release to Nuttall, (I late Dec, early Jan) we give the same answer as we gave him.

Are you happy with this, or can you suggest something better (ie simpler)? I know it sound a bit cloak-and-dagger but its just meant to save time in the long run.

Im copying this to DEP and CKF also for comments.

Cheers

Geoff

Hm, clearly coordination between the two (if it really ends up as two) groups is absolutely essential, otherwise we would look entirely stupid. The first thing that comes to my mind is that nitrogen would be emphasizing a component of our overall idea which otherwise would not receive great attention - hence it could be, perhaps, amalgamated. They probably see it the other way around: In their problem, climatic variability comes second in importance. My view on this is that all of our model intercomparisons have shown that models essentially do crazy things with interannual variability, simply because nobody ever has tested them for that in any detail. Esser's model would probably be the last candidate to use here, since it is "less mechanistic" than any of the others - in fact, Colin and I seemed to agree to "not necessarily" include it into this proposal. These are just some thoughts for the moment.

I just finished a very first, rough draft of our outline, and I attach it to the end of this message. I have just sent it to Martin Heimann, but I have still not yet talked to him. I also send this whole thing to Colin, hoping that he will catch the thread through it without problems. Gerard Dedieu is the one I want to approach next - Alberte is already talking to him about this in the context with other things.

Cheers,

Wolfgang

Global, spatially explicit assessment of the interannual
variability in terrestrial carbon storage

VERY FIRST, INCOMPLETE draft for a new research proposal
to be submitted to the European Union
for the second phase of the Third Framework "Environment and
Climate"

Goal

A critical uncertainty in assessments of global change impacts and feedbacks is the source/sink relationship for carbon between atmosphere and the terrestrial biosphere, and particularly its interannual variability. Recent advances in modelling of atmospheric and biospheric processes, combined with significant progress in data gathering for climate, CO₂ and O₂, now allow for a dedicated experiment that is likely to reduce this uncertainty. Equilibrium approaches to the simulation of global carbon fluxes are no longer adequate for this, since empirical studies are showing both a long-term trend and a significant interannual variability of CO₂ fluxes, which appear to be most strongly driven by climatic impacts on terrestrial vegetation.

Experimental design

For a time period of several decades, we propose to perform a simulation of biospheric carbon fluxes using:

- ú a range of currently available biospheric models (ongoing intercomparisons indicate that there is no clear 'best approach' - therefore this project will use several approaches <<<and we would like to include the CESBIO people for the testing of all model outputs against global seasonal fPAR observations - or does this overload the project?>>>),
- ú a realistic, historical high-resolution climatology (which so far does not exist - a recent IGBP-workshop has however clearly identified the need for it and what would be necessary to achieve it within a short time-frame),
- ú a land use map from currently available observations <<<or from satellite?>>>),
- ú a 3D atmospheric transport model for the calculation of net CO₂ concentrations at the stations where these are observed <<<and of course those measurements themselves>>>.

Land use and different climatic elements will be combined in factorial combinations to investigate the role of each element in the full system response.

<to be continued... A critical question to me at this time is whether the project should go for two timeframes: if there is, in addition to the timeframe of available CO₂ measurements, also a 10 year timeframe, then we could compare all models against available seasonal fPAR profiles from satellites and hereby assess their capacity to recover other aspects of

biospheric dynamics. Another question is whether we should also throw in a GCM experiment to allow for future scenarios.>

Expected results

- ú Improved understanding of the global carbon cycle - realistic seasonal and interannual simulations are essential for identifying regional responses of the terrestrial biosphere

- ú From that: Improvements of mitigation assessments such as those required by the IPCC

- ú Global, historical, high-resolution climatology which is required by other assessments of impacts of global change

Consortium participants

Contractors

- ú Potsdam Institute for Climate Impact Research (PIK), Potsdam, Germany (Wolfgang Cramer): Project coordination, experimental design and analysis

- ú Climatic Research Unit, University of East Anglia (CRU-UEA), Norwich, UK (Michael Hulme): Development of a global high-resolution historical climatology

- ú Max Planck Institute for Meteorology (MPIM), Hamburg, Germany (Martin Heimann): Atmospheric transport model, ocean component, analysis of results against measurements, TBM simulations using SILVAN

- ú possibly a fourth one (CESBIO, Toulouse?) if we decide to go for a significant remote sensing component

Subcontractors

- ú Department of Ecology, Lund University, Lund, Sweden (I. Colin Prentice): TBM simulations using BIOME3

- ú Institute of Terrestrial Ecology, Edinburgh, UK (Andrew Friend): TBM simulations using HYBRID

- ú Department of Chemistry, Frankfurt University, Frankfurt, Germany (Gundolf H. Kohlmaier): TBM simulations using FBM

- ú Sheffield University, Sheffield, UK (F. Ian Woodward): TBM simulations using Sheffield-DGVM or DOLY

- ú (if politically possible:) Center for Resources and Environmental Studies, Australian National University (ANU-CRES), Canberra, Australia (Michael F. Hutchinson): Development of suitable scaling algorithms for climatic data assimilation

Dear Keith,
 we received your letters concerning our paper for Dendrochronologia and three long chronologies.

1. As regards individual ring width data of living trees from Yamal we would remind you that you have them. Stepan gave to you in England one diskette. There are data for *Larix sibirica* from three sites (KHA - from Khadyta river, 67812'N 69850'E; JAH - from Yahody river 67807'N 69854'E and POR - from Portsya river 67827'N 71800'E) and for *Picea obovata* from two points (SCH - Shtshutshya river 66849'N 69850'E and KHD - from Khadyta river 67807'N 69854'E).

2. We would be very grateful if you can do some corrections and additions in the paper for Dendrochronologia. We did not quite understand what we have to do on missing rings? Just enumerate years when missing rings occur? If so, these are following years:

Year absent	%	ind	%	Year absent	%	ind	%
-1172	1 of 4	25%	51	700	2 of 8	25%	31

We have to note that frequency of missing rings on increment cores of living trees higher, because on samples of subfossil trees we try to find this kind of rings on whole disc.

Some periods are notable for missing rings: 988-964 BC, 882 BC, 143 AD, 623-646 AD (especially 640 AD), 814-816-818 AD, 1453 AD and beginning of 1800th AD.

3. Stepan ask what about book by Bailey?

Best wishes,

Rashit

Subject: the paper
Date: Mon Dec 9 15:17:42 1996

Dear Rashit and Stepan

Thanks for the message and the missing data info. I will make some additions and include a plot/list of these missing years. I assume you don't mind me including your plot of the recent Yamal curve and statistics about crossdating with Polar Urals. I'll send ammended paper as soon as possible. Thanks for the quick reply. Do you have a working fax? best wishes to you all

Keith

To: d.viner@uea.ac.uk (David Viner - Climate Impacts LINK Project)
Subject: ECLAT 2
Date: Wed, 11 Dec 1996 11:11:18 +0200
Cc: m.hulme@uea.ac.uk

Dear David/Mike,

Thanks for sending me the ECLAT 2 proposal. First, let me say that I support the idea of a continued role for activities co-ordinating and facilitating the provision of climate change information for EC impacts research and other related research and policy. ECLAT 2 is one way of achieving this, but the fact that it is a Concerted Action Initiative imposes some limitations.

The major limitation is that CAIs are not supposed to involve original research. They are networking activities, with a view on forging research links and developing new research projects. In my view, there is a need for a number of targetted research activities on scenario development, that might be covered by the themes of the workshops you are suggesting in ECLAT 2, but which would be best served by some dedicated research projects. It really isn't satisfactory to wait until the end of ECLAT 2 before embarking on research. Many of the key topics are already known, and although research may be proceeding in some of these areas (especially in downscaling techniques, scenario development techniques, etc.), what is still lacking is co-ordination across Europe in the selection and application of climate change scenarios in impact assessment. In my view, there are two areas in sore need of targetted research:

(1) A project to analyse all available information from GCMs and historical data, which will provide some uncertainty bounds on the anticipated future climate in Europe (by region) for use in policy as well as in impacts assessment. Such a project should involve GCM groups (interpreting the GCM outputs), scenario developers (who can apply methods of generalising across a lot of GCM predictions and emissions scenarios, etc.), and a few impact analysts, who can advise on suitable scenarios for use in a variety of applications (entry level or basic scenarios).

(2) A project to develop guidelines for impact analysts on the application of climate change (and related) scenarios in European impact assessments. This work would need to be linked closely to any co-ordinated, entry-level scenarios selected for use in EC projects.

However, unless you have a project proposal in the pipeline at CRU (?) I don't think there is now time to develop a new proposal to meet the 15 January deadline.

Comments on the draft document:

1. It is unclear to me how Figure 1 relates to the text. The arrows are not well differentiated in the fax version I have, and the boxes are not explained.
2. Similarly, Figure 2 is also misleading. It implies that there is a large transfer of information from the CC modelling community to the CC impacts community, but surely the whole function of the ECLAT SE would be to act as a filter in this transfer. Note that the title of the figure should be revised.
3. PLEASE REMOVE the reference to ECLAIR - there is no such name! This was a light-hearted emailed suggestion for ECLAT 2, not for Martin's CA which doesn't have a name to my knowledge.
4. In the suggested steering committee, I would strengthen the representation of the impacts community. This could be done by time horizon: e.g. one hydrologist to cover a range of time periods from sub-daily to century scale; one forester or soils expert for the long term, one agriculture person for the medium term (maybe I could represent this community), desertification/erosion/fire risk person for short to medium term and/or an integrated assessment person (perhaps three or four persons). You should try to avoid the group being dominated by GCM'ers (do all GCM groups have to be represented?)

You might ask Ib Troen if there would be any opportunity to obtain EC funding BEFORE THE FIFTH FRAMEWORK CALL FOR PROPOSALS for a targeted research topic, if this was strongly and urgently recommended by a task group workshop. Might there be special funding from DG XI, ENRICH or the Environment Agency?

Best wishes,

Tim

Subject: RE: Scengen and CC:Train
Date: Thu, 16 Jan 1997 10:00:48 +-1300

Dear Mike,

Thanks for your detailed reply concerning Scengen and CC:Train. I was not proposing to incorporate Scengen in a major way into the training package, and I am quite aware of the problems of consistency regarding aerosol effects, natural variability, etc. Rather, I thought that the training package would be an excellent way to introduce the existence of Scengen (and MAGICC) to the Country Teams which are responsible for coordinating national assessments. (the intention was NOT to provide intensive technical training in its use -- the country team members are largely coordinators, not technical climate experts). In this way, when it comes time to actually carry out the national assessments, Scengen would be recognised as a major tool for scenario generation and, if appropriate, CRU could be contacted regarding its application, technical training or collaboration. You had mentioned to me at the IPCC meeting in London that one of your major aims was to get Scengen recognised as the "standard" for scenario generation for impact assessments, and I simply thought I saw a way of furthering that aim through the CC:Train mechanism.

Given the training programmes that you are currently proposing through ENRICH and others, I can understand your fears that we might "muddy the waters". Let me pose the following options; that we

- (1) use some hard-copy examples from Scengen;
- (2) incorporate a demonstration diskette (do you have one?);
- (3) just mention the existence of Scengen;
- (4) not mention Scengen at all.

Frankly, I am quite happy with any of these. The part on climate change scenarios is really only a small bit of the overall V&A training package in any case.

Good luck with your proposals.

Cheers,
Dick

Subject: Re: Scengen and CC:Train

Dick,

And Happy New Year to you also.

You've posed me a tricky one re. SCENGEN and my answer about it being incorporated into the CC:Train package as a component tool is going to have to be 'no'. Let me explain.

We too here have plans to exploit SCENGEN (and MAGICC) in a training/educational context. I ran a pilot seminar here for UNEP before Christmas on scenario construction, although this was using the new WINDOWS/Unix versions of both MAGICC and SCENGEN (MAGICC 2 and SCENGEN 2; IPCC 1995 compatible) we have re-written. Also, I have just submitted a proposal (called SPARCCS) to ENRICH in DGXII for a support package for regional climate change scenarios. This would be a 2-year project with emissions people, as well as MAGICC, SCENGEN and our new global historic climatology. I think we have a good chance of funding.

With this background I do not want SCENGEN (and especially the old DOS version) 'leaking' out into the climate training community at this stage.

I am confirmed in this view by thinking that the complex issues surrounding scenario creation (and the new IPCC Taskgroup on scenarios for the 3rd assessment is grappling with these - ask Tim Carter about it) should not be an essential part of a vulnerability/adaptation package. And even if you think differently then let me suggest the following: if you think it should be a minor part then I do not think that you need SCENGEN formally incorporated; if you think it should be a major part then not only do I think you are wrong in thinking so, but there is more to the scenario issue than can be supplied by SCENGEN - for example, you need MAGICC, you need to consider how you handle aerosols, and you need to think about natural variability and signal/noise issues.

My feeling is that by all means use SCENGEN within CEARS in thinking about the training package and coming up with some off-line examples (either

sample scenarios or guided sensitivity), but do not incorporate it in the package. [By the way SCENGEN does not have imaginary countries!]. If people want more detailed thinking on scenarios then you could always refer them to CRU (which is what our speciality is).

I hope you understand my feelings on this - I am not trying to be negative, but am thinking ahead and about the complexity of the scenario issue. I have talked with Tim Carter recently at some length about some of these things so I will copy this correspondence to him.

Good luck with CC:Train anyway and I'm sure you'll come up with something good.

Regards,

Mike

Subject: Russia

Date: Sun, 26 Jan 1997 14:16:32 -0500

Hi Keith:

As you are aware, the situation in Russia is very uncertain with their unfortunate economic condition, especially science support. There is interest, hope, and dots on maps showing intent but actual activity is difficult to judge. In the particular area I am interested in, the Taymyr, there is no current active tree-ring research going on although it has been previously sampled and some reports are in preparation. Ed probably told you that I have submitted a proposal to do work there. My understanding is that unless there is some external funding support, such as my project, tree-ring sampling there is in abeyance. Several people, including yourself, recognize the great potential in the region. From my perspective it seems that the Polar Urals are being studied, Yakutia to the far east is being studied, some work has been done by Szeicz and Macdonald at the Lena but there is need for more intensive effort in Taymyr. I would like to hear your perspective on the situation.

In a related topic, I am thinking of using the option in Ed's new ARSTAN to use the regional standardization method. In Russia and other locales the establishment of trees is episodic. In particular, in Alaska Glenn Juday has data showing cohort groups being established in favorable times. In Taymyr also, the establishment of trees is not evenly distributed through time. There are times of growth and times of demise. This concerns me as it could affect the development of a regional curve. do you see problems arising from this?

I am also curious to hear any comments you care to make about my recent letter to Fritz Schweingruber. He obviously will pursue any style of sampling and analyses he chooses to. My only contention is that he should not represent his data as the definitive tree-ring information, particularly ring-width data. His opinions are influential but there is an accumulating body of ring-width data that clearly shows him to be missing much important information with his style of sampling. Scientists and others should be aware of this fact.

Cheers, Gordon

4.1. TITLE OF THE PROJECT

Multi-millennial-length dendroclimaticreconstructions at high-latitude regions of Siberia

4.2. SUMMARY

This research will make a major contribution to our knowledge of high-resolution climate variability at high latitudes of Western and Middle Siberia throughout the Holocene using the unique potential of tree-ring data.

The specific objectives of this proposal are the development of two supra-long (each spanning 6-9000 years up to present) continuous larch ring-width chronologies at two distant each other high-latitude locations of Siberia (Yamal and Taimyr peninsulas). Ring-width chronologies developed from coniferous trees growing at the polar timberline in Siberia contain a very strong climatic signal, mainly summer air temperatures. With these chronologies high-resolution continuous and quantitative

reconstruction of summer temperatures will be made.

As in the areas of the past and present polar and upper timberlines trees megafossils have been preserved properly in large quantities in the Holocene deposits (alluvial, lacustrine and peat), there is a good possibility to develop continuous, multi-millennial tree-ring chronologies.

Now the material already collected and measured (1800 subfossil wood samples from Yamal and 280 samples from Taimyr) has yielded the ring-width chronologies continuously spanning the last 3200 years (Yamal) and 950 years (Taimyr).

However, there are also many more samples that have been measured and have provided data, now assembled in a number of provisionally "floating" chronologies covering much of the period from 7000 to 1700 B.C. (based on some 70 radiocarbon dates of samples of this wood). There is a fair chance that a 6-9000-year continuous chronologies will be constructed within the span of the proposed project.

These chronologies and temperature reconstructions will be the first to be so long, reliable, annually-resolved and precisely-dated with known reliability across the whole of northern Hemisphere. These reconstructions will allow to compare and contrast the details of temperature changes at the moderate-continental region of Yamal Peninsula with the continental region of Taimyr Peninsula and allow modern and predicted temperature patterns to be compared with variability patterns of pre-industrial era. Participants of the proposed project are the well-known institutions which are engaged in the field of dendrochronology and dendroclimatology and have collaborated with each other during the last 6 years.

fAJL workpro.txt

3.1 TITLE

Multi-millennial-length dendroclimatic reconstructions at high-latitude regions of Siberia

3.2 OBJECTIVES

This research will make a major contribution to our knowledge of high-resolution climate variability at high latitudes of Western and Middle Siberia throughout the Holocene using the unique potential of tree-ring data.

The specific objectives of this proposal are as follows:

- to develop two supra-long (each spanning 6-9000 years up to present) continuous ring-width larch chronologies at two high-latitude locations of Siberia;
- using these tree-ring chronologies, to make a multi-millennial high-resolution continuous and quantitative reconstruction of summer temperatures;
- to analyse spatio-temporal patterns of temperature variability at these locations over a range of timescales (annual, decadal, multi-decadal and centennial) and their connections with various forcing factors and other annual resolution records being developed elsewhere in the Arctic and Subarctic.

3.3. BACKGROUND

Reconstruction and analysis of natural climatic changes through the whole Holocene at high latitudes are of great importance as climatic conditions, especially air temperature, are most variable and sensitive to various forcing functions (Budyko, 1980; Jones and Kelly, 1983; Intergovernmental Panel on Climate Change, 1990). However, there are a minute quantity of long, precisely-dated and high-resolution proxy climatic series for these regions.

The territory of Yamal Peninsula located on the eastern boundary of influence of the Atlantic air masses and the territory of the eastern part of Taimyr Peninsula located between the Arctic High and Siberian High are of major importance for monitoring regional and global-mean air temperatures and assessing theories and models concerned with past, current and future climate changes (Lamb, 1977; Briffa and Jones, 1993; Moses et al., 1987).

Tree rings as a proxy indicator of the past climatic conditions are of special interest as they allow to reconstruct climatic parameters with seasonal and annual resolution for many hundred and thousand years, to provide an exact absolute and relative dating of the tree-ring data, to establish high-frequency climate changes (from interannual to centennial timescales) with high confidence, to obtain dendroclimatic information practically for

every site where trees grow at present or grew in the past.

Intensive dendroclimatic investigations are carrying out in many countries and regions, mainly in temperate and subtropic zones (Fritts, 1976, 1991). At high latitudes such works began later (during the last two decades) and living trees were used primarily for developing tree-ring chronologies of 200-500 years long (Aniol and Eckstein, 1984; Shiyatov, 1984, 1986; Jacoby and D'Arrigo, 1989; Schweingruber, Briffa and Nogler, 1993; Briffa, Jones, Schweingruber, Shiyatov and Vaganov, 1996; Jacoby, Wiles, D'Arrigo, 1996; Vaganov, Shiyatov and Mazepa, 1996). As in the areas of the past and present polar and upper timberlines trees megafossils have been preserved properly in large quantities on the surface and in the Holocene deposits (alluvial, lacustrine and peat), there is a possibility to develop continuous, multi-millennium and sensitive to climate tree-ring chronologies. Such works began in the Polar Ural Mountains (Shiyatov, 1986; Graybill and Shiyatov, 1992; Briffa, Jones, Schweingruber, Shiyatov and Cook, 1995), in the southern part of Yamal Peninsula (Shiyatov, Surkov, 1980; Hantemirov, 1995), in Finnish Lapland and Northern Sweden (Zetterberg, Eronen and Briffa, 1995), in the eastern part of Taimyr Peninsula (Vaganov, Naurazbaev, Schweingruber and Briffa, in press) and in the Lower Indigirka River at present. Now the longest, continuous and absolute-dated ring-width chronologies developed for the Yamal Peninsula (spanning 3200 years) and for the Northern Scandinavia (spanning 2160 years) and the "floating" chronologies dated by the radiocarbon method extended back 9500 and over 7000 years respectively.

Ring-width chronologies developed from coniferous trees growing at the polar timberline in moderate-continental and continental regions of Siberia contain a very strong climatic signal, mainly summer air temperatures of tree growth year (Graybill and Shiyatov, 1992; Briffa, Jones, Schweingruber, Shiyatov and Cook, 1995; Hantemirov, 1995; Vaganov, Shiyatov and Mazepa, 1996). The explained variance over the calibration and verification periods is highest reported in the literature to date (65-70%) and it allows to make a quantitative reconstructions of summer temperatures. These chronologies and temperature reconstructions will be the first to be so long, reliable, annually-resolved and precisely-dated with known reliability across the whole of northern Hemisphere. These reconstructions will allow to compare

and contrast the details of temperature changes at the moderate-continental region of Yamal Peninsula with the continental region of Taimyr Peninsula and allow modern and predicted temperature patterns to be compared with variability patterns of pre-industrial era.

Participants of the proposed project are the well-known institutions which are engaged in the field of dendrochronology and dendroclimatology and have collaborated with each other during the last 6 years.

- The Group of Tree-Ring and Site of the Swiss Federal Institute for Forest, Snow and Landscape Research (Birmensdorf, Switzerland). The Group is currently engaged on a major programme of densitometric and ring-width chronology development involving many sites across the whole of the Northern Hemisphere including sites with living trees in the polar timberline area of Russia. This work is specifically designed to provide climatically-sensitive data for use in large spatial climate reconstruction work. Dr. F.H.Schweingruber, Head of the Group, is known throughout the world for his work in wood anatomy and dendrochronology and the development of tree-ring densitometry. He has published extensively in different areas of wood anatomy and tree-growth research and has authored several classic books.

- The Laboratory of Dendrochronology of the Institute of Plant and Animal Ecology of the Russian Academy of Sciences, Ekaterinburg, Russia is one of the leading laboratory in the field of dendrochronology in Russia. The Laboratory has an international reputation for its work on the developing ring-width chronologies at high latitudes and altitudes, reconstruction of climatic conditions, developing long-term chronologies, studying cycles in tree-ring series, using tree-ring data for studies of the upper and polar timberlines dynamics and forest succession. Dr. S.G.Shiyatov, Head of the Laboratory, is one of the pioneers of dendrochronology in Russia and has worked for more than 30 years in the Far North and mountains of the Urals, Siberia, Far East and Middle Asia. He has published more than 130 articles and three monographs. Dr. Shiyatov was the first who began to collect subfossil wood in Russia for developing long-term chronologies.

- The Laboratory of Dendrochronology of the Institute of Forest

of the Russian Academy of Sciences, Krasnoyarsk, Russia is another leading laboratory in the field of dendrochronology in Russia. Dr. E.A.Vaganov, Director of the Institute of Forest and Head of the Laboratory of Dendrochronology, has an international reputation for his work on the cell structure of wood layers of coniferous trees, seasonal growth variations and cambium activity, developing simulation models of seasonal tree growth, developing ring-width and cell chronologies, reconstructing climatic conditions of the past using tree-ring chronologies. He has published more than 100 articles and 5 monographs.

- The Climatic Research Unit of the University of East Anglia, Norwich, Great Britain is one of the world's leading research organisation specialising in the study of climate change: climate history, current climates, projected changes and impacts. Dr. K.R.Briffa, Senior Research Associate at the Climatic Research Unit, has considerable experience in climatology and with the use of statistical methods of climate analyses and dendroclimatic reconstruction, especially with regard to large-spatial-scale reconstructions of climate patterns and published many articles on the theoretical and practical aspects of dendrochronology and dendroclimatology, and on use of paleoclimate data for understanding current and possible future climates.

3.4 SCIENTIFIC AND TECHNICAL DESCRIPTION

3.4.1. RESEARCH ACTIVITIES

Tree-ring data will be obtained from living trees and subfossil wood of Siberian larch (*Larix sibirica* Ledeb.) in western Siberia and Gmelini larch (*Larix Gmelini* Pilger) in central Siberia. The first location is situated in the southern part of Yamal Peninsula (67-688N, 69-718E), the second location in the eastern part of Taimyr Peninsula (71-738N, 98-1058E). There is a great many properly preserved subfossil wood in the Holocene deposits at both locations, mainly in the alluvial and peat deposits.

The main variable measured will be ring width. This variable reflects properly climate influences on tree growth at the polar timberline areas of Siberia having a continental climate.

Ring-width chronologies for the last 400-500 years will be developed from the oldest living trees. Extensions to these chronologies back further in time will be made by using subfossil

material, joined with the living material by standard crossdating procedures. High-precision radiocarbon dates will be used for rough dating of "floating" tree-ring chronologies.

The sampling subfossil wood and development of the Yamal's supra-long chronology began since 1982 by the workers of the Laboratory of Dendrochronology (Ekaterinburg). Most intensively this work was carried out during the last five years. Now the material already collected and measured (1800 subfossil wood cuts) has yielded the ring-width chronology continuously spanning the last 3200 years. However, there are also many more samples that have been measured and have provided data, now assembled in a number of provisionally "floating" chronologies covering much of the period from 7000 to 1700 B.C. (based on some 45 radiocarbon dates of samples of this wood). These chronologies separated by 50 to 500 year length gaps. There is a fair chance that a 9000-year continuous chronology will be constructed for this location within the span of the proposed project.

Similarly, work with a shorter history than the Yamal's research has clearly established potential to build a chronology at least as long in the Taimyr Peninsula where the modern polar timberline extends to about 72°30'N, most northern over the world. This work is not so advanced as in Yamal, but the work to date suggests that very rapid progress is likely. Samples from living and dead trees have already been assembled at the Laboratory of Dendrochronology (Krasnoyarsk) into the 950-year continuous chronology. The collections from this location are not so extensive as those made to date at Yamal (280 subfossil wood samples), but there is an abundant supply of subfossil trees, many with over 300 annual rings. 25 radiocarbon dates of samples of this material suggest major phases of tree growth around 8500 B.P. and 5000 B.P. The general distribution of the radiocarbon dates suggests that, eventually, sufficient trees can probably be located to span the whole of the last 10000 years. It is not expected that a continuous 10000-year ring-width chronology will be produced within timeframe of this project. However, there are good prospects of producing a 5-6000- year chronology to the present.

3.4.2 RESEARCH RESULTS

During three years we expect to develop the continuous and good-replicated tree-ring 9000-year larch chronology for the

Yamal Peninsula and the 5-6000-year larch chronology for the Taimyr Peninsula. Using these chronologies we intend to reconstruct and analyse a summer temperature variation at several time scales (annual, decadal, multi-decadal and centennial) and compare the data obtained with other high-resolution Holocene-length proxy data (ice cores, laminated sediments, historical documents).

The results of this project will be published primarily in the scientific literature in Russian and English and presented at different national and international conferences. Because of the fundamental interdisciplinarity and collaborative interaction within the subgroups, a number of multi-authored papers will be produced. The individual and mean ring-width chronologies and the reconstructions produced will be distributed to the international scientific community through submission to the International Tree-Ring Data Bank (Boulder, Colorado, USA) and to other national and international institutions and data centres.

3.5 MANAGEMENT INFORMATION

3.5.1 TASK DIVISION

Dr F.H.Schweingruber (Swiss Federal Institute for Forest, Snow and Landscape Research) will be the project co-ordinator on the proposed project from the INTAS countries.

Dr S.G.Shiyatov (Institute of Plant and Animal Ecology) will be the responsible scientist on the proposed project and he will take part in collecting, dating, developing and analysing the multi-millennial ring-width chronology at the area of Yamal Peninsula. The next young scientists of the Institute will be involved in the project:

Rashit M. Hantemirov, Candidate of Biological Sciences, 34 years old. He will take part in collecting, cross-dating and analysing the material.

Alexander Yu. Surkov, technician, 30 years old. He will take part in collecting, preparing and measuring the subfossil wood samples.

Dr E.A.Vaganov (Institute of Forest) will be the responsible scientist on the proposed project and he will take part in collecting, dating, developing and analysing the multi-millennial ring-width chronology at the area of Taimyr Peninsula. The next young scientists will be involved in the project:

Mukhtar M. Naurazbaev, junior research fellow, 35 years old.
He will take part in collecting, preparing, measuring, cross-dating and analysing the material.

Alexander V. Kirdyanov, post-graduate, 25 years old.
He will take part in data processing, density measurements, chronology analysis.

Dmitry V. Ovchinnikov, post-graduate, 26 years old.
He will take part in cross-dating, data processing, chronology analysis.

Dr K.R. Briffa (Climatic Research Unit) will be the responsible scientist on the proposed project and he will take part in analysing growth-climate relationships, developing statistical models of tree growth, extracting climatic signal, reconstructing and analysing climatic conditions of the remote past.

3.5.2 PLANNING

To carry-out the objectives of this proposal the workers of the Russian laboratories will carry out an intensive collecting subfossil wood during summers of 1997-1998 at two high-latitude locations (Yamal and Taimyr peninsulas) using helicopters, boats and ships. To finish the development of the Yamal chronology it is necessary to collect additionally no less than 300-400 cuts of subfossil wood. Much more intensive collecting (600-800 cuts for two field seasons) is needed to develop the Taimyr chronology. All samples collected during these two years and earlier will be measured and cross-dated at Ekaterinburg and Krasnoyarsk laboratories until the middle of 1999.

The Russian laboratories together with the Climatic Research Unit of the University of East Anglia during 1997-1999 will be analysing the material obtained (standardization of individual series, development of mean chronologies, studying growth-climate relationships, developing statistical models of tree growth, extracting climatic signal, reconstructing and analysing climatic conditions of the remote past). This work will be finished at the end of 1999.

3.5.3 EQUIPMENT

Participants of the proposed project have the necessary equipment for fieldwork, measuring equipment and compatible software.

Dear Keith,

After our long silence we would like inform you about our successes, problems and plans.

1. The main success to our mind is the next. We have filled up the gap (1350-1250 BC) between the absolutely dated 3250-year Yamal chronology and the nearest floating chronology. It was happened few weeks ago using samples collected in 1996. Now there are no obstacles to develop in the nearest future the 7000-7500-year length continuous chronology. Now we are working with ancient samples: searching the places of missing and false rings, making more precise datings of individual chronologies and so on. During this time interval we have some problems. For example, no more samples were found up to now to confirm the absence of false ring near 360 BC.

2. This summer we intend to hold an expedition from the end of June to the middle of August in the southern part of Yamal peninsula to collect more samples of subfossil wood which have a great many of rings, are sensitive and cover the intervals represented by insufficient quantity of samples at present. We think that during this field season we must collect a necessary quantity of samples to develop a well represented 7000-7500 years chronology. Next year we intend to collect subfossil samples of wood from the middle part of Yamal peninsula to reconstruct the dynamics of polar timberline during the Holocene in detail using a large number of tree remnants absolutely dated by dendrochronological method.

2. This year we have a small grant the from the Russian Science Foundation for developing the Yamal supra-long chronology (approximately 4000 USD). But we are not sure that all this sum we will receive. For example, last year we have received 37% from the promised sum of money. As cost of helicopter's rent is increased again this year (about \$ 2.000 for one hour), we have the problem how to reach our research

area in the Yamal peninsula. E. Vaganov have the same problem with organisation of field works over the territory of Taimyr peninsula. That is why we and E.Vaganov ask you to transfer each of us 7-8.000 USD until the end of June from the ADVANCE project, if it is possible. Last summer, when I was in England, you promised to help us with money to organise field works this year.

3. I am finishing a measurements of rings of subfossil wood samples collected last year on the surface and in one lake and some bogs in the Polar Ural Mountains. I found a little more ancient wood (not all samples are dated until now) and can prolong this chronology at least up to one hundred years. This summer I will be in the mountains and try to collect wood from other lakes. I want to develop the Polar Urals chronology for the last 2.000 years.

4. Now we are preparing the paper concerning Yamal project in Russian and we need to cite the paper prepared for Dendrochronologia in English. Could you send to us the last version of this articles by e-mail or by post?

We wish you and your family the best. We wish the same to Phil Jones and his family.

Sincerely yours

Stepan Shiyatov and Rashit Hantemirov

Dear Keith,

Thank you for the message of 5 June, 1997.

I am understanding your difficulties with transferring money and I think the best way for us if you will bring money to Krasnoyarsk and I give you a receipt.

Rashit will go to Yamal at the end of June and I go to the Polar Urals at the beginning of July. We can find money temporary at our Institute and other sources for three months to fulfill our fieldworks. Now I am at two weeks holiday with my wife and granddother near Moscow after the meeting of Russian Academy of Sciences where E.Vaganov was elected as the Academician. It is important for dendrochronological studies at our country and international collaboration.

Sincerely yours Stepan Shiyatov

Dear Tony and Michael,

The final draft of the letter to the Times is attached, incorporating your changes (I hope I have combined them in a way that you are both happy with).

Brian Hoskins and Adrian Jenkins have both decided that they prefer not to sign the letter, although agreeing with its message. I haven't been able to contact anyone else in the short time available, so I leave it up to you to decide whether you are still both happy to go ahead.

If so, Mike could you please reply to both Tony and myself and let us know, and Tony could you then send it as agreed?

Thank you both very much for your time and trouble.

Best regards,
Helen

21 June 1997
Dear Sir,

Without wishing to comment on the dispute between BP and Greenpeace (Editorial, 20 August), we would like to remind your readers of the seriousness of the potential threat caused by our continued use of fossil fuels. This damage occurs both locally - as evidenced by the deterioration of air quality in UK cities in the past few weeks - and also globally.

As scientists studying the impacts of climate change, we consider the global threat from greenhouse gases to be serious and to need addressing. Adverse effects on human populations are likely to result from changes in weather patterns, shifts in storm frequencies, rises in sea level and the spread of certain pests and infectious diseases. A wide variety of ecosystems throughout the world will be at increasing risk.

We have little idea whether or not we can manage such adverse effects and therefore the prudent course of action is to limit the cause of the threat.

Major shifts in investment away from fossil fuels will therefore be required to make the necessary reductions in emissions of carbon dioxide to the atmosphere. Large companies like British Petroleum seem to us to be well placed to take an active part in investing in these changes. There is no doubt the need for precautionary, preventative action is urgent.

Yours sincerely,

<x-rich>Dear Colleagues,

I would like to take this opportunity to thank all of you who have attended the

SRES Lead Authors' meeting (17-19 September 1997) and Rob Swart and his colleagues from RIVM for organizing and hosting the meeting.

We have achieved a lot in the three short days as you will soon also see from the minutes. The minutes of the meeting will be forwarded to you later this week

together with the revised SRES work plan that we have discussed during the meeting.

Sorry that it took a while longer this time for the completion of the minutes,

but I hope that they will refresh you memory about the outcome of the meeting.

Erik Haites just e-mailed that he returned from the IPCC plenary meeting in

Maldives and that the new IPCC Bureau has been appointed. It consists of

30 members: the Chair (Bob Watson), 5 Vice-Chairs (R. Pachuari (India), R.

Odingo (Kenya), G. Meira Filho (Brazil), Y. Izrael (Russia), K. Seiki (Japan), and 8 Bureau members for each of the three Working Groups. The Bureau for Working Group III (responsible for SRES) is B. Metz (Netherlands), O. Davidson (Sierra Leone), E. Jochem (Germany), M. Munasinghe (Sri Lanka), E. Calvo (Peru), R. Madruga (Cuba), R.T.M. Sutamihardja (Indonesia), and L. Lorentsen (Norway).

Best regards,

Naki

Subject: climate: Japanese proposal

Message-ID: <199710051347_MC2-22DC-A5E4@compuserve.com>

MIME-Version: 1.0

Content-type: text/plain; charset="iso-8859-1"

From: Andrew Kerr, WWF Climate Change Campaign

re.: "scandalous" Japanese climate change proposal

Dear All

I am in Japan for the next week. If you need to, you can contact me by phone at the following numbers:

- * Monday - +81 10 760 5022 (Yurika's mobile)
- * Tuesday-Thursday - via WWF Japan. Tel: +81 3 3769 1711; fax: 3326 1717.
- * Friday - Tokyo Grand Hotel. Tel: +81 3 3456 2222

Tomorrow the Japanese government is due to formally announce its emission reduction proposal for the industrialised world for the Kyoto climate summit: a maximum of a 5% reduction from 1990 levels for a basket of three greenhouse gases over the period 2008-2012. In a second period up to 2017, industrialised countries would not be obliged to make further reductions.

See below for fuller details and an analysis of the emission reduction implications for various industrialised nations.

The information has been well-leaked. In a talk to the Foreign Correspondents Club of Japan last Friday I described the proposal as a "joke". This was well picked up by the written press here.

Now more details have emerged, the proposal is even weaker than first thought. We are faxing a press release out this afternoon to Japan-based

agencies and press with WWF's reaction (see below). You might like to join in the condemnation of what Japan is proposing and ensure that your country flatly rejects the proposal.

Japan's Special Ambassador, Toshiaki Tanabe, is on a world tour canvassing for the support of other industrialised nations. After visiting Washington DC he moved on to Hawaii a few days ago for an informal conference including Australia, New Zealand, Canada and the US. Today's Yomiuri Shimbun gave front-page coverage to Australia's outrage over the stringency of the Japanese proposal!

Tanabe is moving to Europe for talks in the next few days. It is vital that European governments reject the proposal in no uncertain terms and urge Japan to at least support the EU standpoint. (Note: the WWF policies and measures study for Japan identifies how to cut CO2 emissions 8.8% below 1990 levels by 2005 and 14.8% by 2010 - very similar to the EU position). It would also be very useful if progressive business groups would express their horror at the new economic opportunities which will be foregone if Kyoto is a flop.

Best wishes, Andrew

CLIMATE CHANGE: JAPANESE PROPOSAL FOR KYOTO

To be formally announced by the Japanese government, Monday 6 October 1997

Following information is from the Nikkei Journal, 4 October 1997

A. Content of the proposal

1. First period: the five years from 2008 to 2012

Reduction of 5%; Base year: 1990

- 1) Gases: CO₂, methane, Nitrous oxide
- 2) Target figures will be flexible according to the future energy situation, changes in industrial structures, etc. But in any case, the total emission should not exceed 1990 level.
- 3) Each country's target would be based on emission per GDP, emission per capita, and population growth rate.

If emission per GDP of 1990 (A) is smaller than emission per GDP of all countries (B), the reduction rate should be $5\% \times (A/B)$

If per capita emission of 1990(C) is smaller than per capita emission of all countries (D), the reduction rate should be $5\% \times (C/D)$.

If population growth rate from 1990 to 1995 is more than the population growth rate of all other countries, the reduction target of that country should put into consideration their high population growth rate.

Banking, Borrowing, Joint Implementaion and Emission Trading schemes should be introduced with certain conditions.

2. Second period: 2013-2017

Emission should not exceed the level of the first period.

More sophisticated differentiation scheme should be adopted for the second period.

B. Implications of the proposal

Resulting emission reduction targets for the five years 2008-2012, relative to 1990:

	%
Australia	1.8

Czech Republic	5.0
Denmark	2.5
Germany	3.1
Italy	2.5
Japan	2.5
Portugal	1.6
Russia	5.0
Spain	2.2
Switzerland	1.3
UK	3.7
US	2.6

Overall reduction for all industrialised countries: 3.2 %

WWF PRESS RELEASE

JAPAN PROPOSAL FOR KYOTO SUMMIT SCANDALOUS, WWF SAYS

KYOTO, JAPAN, 5 October 1997 ? The World Wide Fund for Nature condemned as "scandalous" the Japanese government's proposal for reducing greenhouse gases responsible for climate change, Sunday, and called on industrialised nations to flatly reject it.

As full details of the proposal emerged over the weekend, it was revealed that Japan suggests allowing industrialised countries to make extremely marginal reductions in their emissions by as late as 2008-2012. In a second five-year period up to 2017, countries would only be required to ensure their emissions were lower than in 1990.

"The Japanese plan presents a bleak future for the environment, already

suffering from the serious impacts of global warming including rising sea-levels, rising sea temperatures, and increased extreme weather patterns ? to name just a few," said Andrew Kerr of WWF's international Climate Change Campaign. "The plan is laughable when you consider that some European nations already have cut their greenhouse gas emissions by several times more than the amount Japan proposes for emission reductions more than a decade from now."

According to the just released "WWF State of the Climate" report that evaluates the global impacts of climate change, a long list of impacts already are visible today including the destruction of several land and marine ecosystems in Asia and around the world because they cannot keep up with the pace of global warming.

The Japanese proposal also proves the government is back-tracking on a Ministerial Declaration concluded at the 1996 climate summit in Geneva. At that conference, 130 countries, including Japan, agreed that the Kyoto Summit should agree on "legally-binding objectives for emission limitations and significant overall reductions" of greenhouse gases. At the Geneva meeting, the Ministers recognised that climate change science showed human activities, primarily the burning of coal, oil and gasoline, are already affecting the planet's climate and the impacts would be wide-ranging and irreversible, posing threats to food supplies, public health and the survival of many species. Nations also agreed that "significant reductions in net greenhouse gas emissions are technically possible and economically feasible".

WWF is calling on industrial nations to cut their carbon dioxide emissions

20 percent below 1990 levels by 2005. A WWF report written by Dr. Haruki Tsuchiya of the Research Institute for Systems Technology, in Tokyo, (to be released by WWF later this month) shows that Japan can reduce its carbon dioxide emissions by nearly nine percent by 2005 and by almost 15 percent by 2010 without damaging the economy. Policies and measures suggested by the WWF report would stimulate the economy and help position Japan as a world leader in the development of new, energy efficient technologies.

"Environmentally, Japan's plan is worse than no plan whatsoever because it pretends to legitimise an emissions cut that is so low it will produce no tangible result in the effort to combat climate change," said Kerr. "Even more alarming, it encourages many nations also to cut their emissions by much less than they now plan. This proposal is an embarrassment for Japan because it spells disaster for the Kyoto Summit in December which will be seen as an absolute failure by several European nations and the entire environmental community if such meagre greenhouse gas emission cuts are adopted."

The complicated emission-reduction formulae that Japan proposes would require Japan to make only a 2.5 percent cut in emissions. The United States, responsible for over one-fifth of world releases of carbon dioxide, would only need to make a 2.6 percent reduction. Highlighting the political irrelevance of the Japanese formula, Germany, Denmark and the UK would have to make reductions of 3.1 percent, 2.5 percent and 3.7 percent respectively. But Germany already has achieved around half of its national target of cutting carbon dioxide emissions by 25 percent by 2005. Denmark is aiming for a 20 percent reduction by the same date and the UK's target

is a 20 percent cut by 2010.

Subject: Timing, Distribution of the Statement
Date: Thu, 9 Oct 1997 18:52:33 0100
Reply-to: alcamo@usf.uni-kassel.de

Mike, Rob,

Sounds like you guys have been busy doing good things for the cause.

I would like to weigh in on two important questions --

Distribution for Endorsements --

I am very strongly in favor of as wide and rapid a distribution as possible for endorsements. I think the only thing that counts is numbers. The media is going to say "1000 scientists signed" or "1500 signed". No one is going to check if it is 600 with PhDs versus 2000 without. They will mention the prominent ones, but that is a different story.

Conclusion -- Forget the screening, forget asking them about their last publication (most will ignore you.) Get those names!

Timing -- I feel strongly that the week of 24 November is too late.

1. We wanted to announce the Statement in the period when there was a sag in related news, but in the week before Kyoto we should expect that we will have to crowd out many other articles about climate.
2. If the Statement comes out just a few days before Kyoto I am afraid that the delegates who we want to influence will not have any time to pay attention to it. We should give them a few weeks to hear about it.
3. If Greenpeace is having an event the week before, we should have it a week before them so that they and other NGOs can further spread the word about the Statement. On the other hand, it wouldn't be so bad to release the Statement in the same week, but on a different day. The media might enjoy hearing the message from two very different directions.

Conclusion -- I suggest the week of 10 November, or the week of 17 November at the latest.

Mike -- I have no organized email list that could begin to compete with the list you can get from the Dutch. But I am still willing to send you what I have, if you wish.

Best wishes,

Joe Alcamo

Subject: (Fwd) Re: Your Holocene paper with Barnett et al 6.3 1996 page 255

Date: Tue, 14 Oct 1997 16:17:44 -0700

Dear Dr. Ritson,

Your email to Phil Jones suggests that there are serious discrepancies between the ECHAM1/LSG power spectrum that I computed for the 1995 Barnett et al. Holocene paper and the ECHAM1/LSG power spectrum that Curt Covey posted on the WWW. This is not the case. At the time that Tim Barnett, Phil Jones, Keith Briffa and I performed the research that is the subject of the Holocene paper, only 600 years of control run data were available from ECHAM1/LSG. This is stated on page 256 of the Holocene paper. The first ca. 200-250 years of this control integration incorporated a large, non-linear climate drift component. This was manifested both in globally-averaged temperature and in other climate variables (see Santer et al., 1995, JGR 100, 10,693-10,725).

Prior to computing the spectrum I removed the overall (i.e., 600-year) least-squares linear trend. There is still considerable low-frequency variance in the residuals, in part (but not wholly) due to the non-linearity of the drift component in the first few centuries. This residual drift explains some portion of the GFDL-versus-ECHAM1 power discrepancies at timescales of >100 years.

The CMIP project received data from MPI well after the completion of the research described in the Barnett et al. paper. At that time, I believe that 1,250 years of ECHAM1/LSG control run data were made available. My understanding is that Curt did not use the first (drift-contaminated) 250 years of the ECHAM1/LSG control run when he computed the ECHAM1 spectrum displayed on the CMIP WWW page. His analysis relied on the last 1,000 years of the data.

Not surprisingly, neglecting the first 250 years makes a big difference to the computed spectrum. This is particularly apparent at low frequencies, and also in the variance ratio (between periods of 300 and 2 years) that you compute.

I hope this clarifies things. Should you still have residual concerns about our method of spectral analysis (which is standard and follows Jenkins and Watts), I'd be happy to provide you with a copy of the program that was used to generate the spectra.

Sincerely,

Ben Santer

Tom

please do. Actually I would be interested to know whether Malcolm mentioned these results to Dave as he was in Krasnoyarsk a few months ago when I showed this stuff. I will be over in New York in a few weeks to discuss with Ed the possibility of putting in an NSF/NERC proposal to look at the tree biomass change question. Also, the initial impetus to redo this stuff was as part of a NERC project we have running in collaboration with Ian Woodward - i which we are inputting high resolution climate data to Dolly to assess the roll of such variability on carbon uptake

Mike,

Thanks.

I am always worried about this sort of things. Even if you have 1000
signitures, and appear to have a strong backup, how many of those asked did
not sign?

Also, I happen to be of the opinion that the US proposal for Kyoto is too
ambitious. But of course I am thinking of real policies, not of
negotiation-rhetoric.

Finally, I think that the text conveys the message that it is a scientific
defense for the EU position. There is not any. Even DG11 finds a hard to
defend (at least, in the draft version of their attempt -- I don't think the
final version has appeared yet). Whatever you think about long-term goals,
2010 is pretty soon. At the moment, no country has any experience with
serious emission reduction POLICY. Minus 15% is serious, particularly because
of the effort that will be spend on the monetary union and because the UK and
Germany are too optimistic on their baseline emissions. Rash action instead
careful thinking may well run serious, international climate policy deep into
the ground.

Cheers

Richard

Mike

> I hope you had my comments from a few weeks ago.

Yes, sorry I've taken so long to reply.

> 1. Overheads: we charge EU projects 20% overheads and these are totally
> acceptable

Yes, you are quite right.

> 2. Budget: I will need to redraft our budget. Please tell me estimated
> start data and for how long the project will run. I envisage our budget
> remaining in the bracket 60-70k ECU

I guess we are looking to April 1998 at the very earliest. I heard that some SMT projects take up to 2 years to get going even after they've been approved due to wrangles over the budget. We have 1 million ECU for 3 years....so some project budgets will have to be cut. Yours looks fine.

> 3. Workplan: I am assuming the basic climate tasks remain pretty much as
> before, namely:
>
> a) 10' gridded monthly climate data for Europe for 1961-90 linked to a weather

> vapour pressure, sunshine/radiation, wind, wet days, frost days.

Yes, that'll do nicely!

> b) for the world a 0.5deg gridded dataset for 1961-90 at monthly timesteps

Excellent!

> c) what was decided about very high resolution climate surfaces for 1-2

- > regions?
- > This was in the original proposal but got dropped I think. Adding this back
- > to our work plan would involve extra time and hence resources. How
- > important are
- > these test 1km (?) resolution datasets?

We've had a problem contacting the Spaniards which is a bit of a blow because they gave a nice geospatial feel to the project. The Norwegians are proposing to conduct a high resolution study near Oslo..I think they'll be interpolating locally collected data. I'll send you their proposal as soon as I can get it into a little better shape but, in principle, I think it would be best if you could, at this stage, just stick to the low resolution work.

- > 4. Other EU projects: I suggest you mention my involvement in CLIVARA
- > which is
- > funded through the Environment/CLimate programme of DGXII. This is running

Dear Eleven,

I was very disturbed by your recent letter, and your attempt to get others to endorse it. Not only do I disagree with the content of this letter, but I also believe that you have severely distorted the IPCC "view" when you say that "the latest IPCC assessment makes a convincing economic case for immediate control of emissions." In contrast to the one-sided opinion expressed in your letter, IPCC WGIII SAR and TP3 review the literature and the issues in a balanced way presenting arguments in support of both "immediate control" and the spectrum of more cost-effective options. It is not IPCC's role to make "convincing cases" for any particular policy option; nor does it. However, most IPCC readers would draw the conclusion that the balance of economic evidence favors the emissions trajectories given in the WRE paper. This is contrary to your statement.

This is a complex issue, and your misrepresentation of it does you a dis-service. To someone like me, who knows the science, it is apparent that you are presenting a personal view, not an informed, balanced scientific assessment. What is unfortunate is that this will not be apparent to the vast majority of scientists you have contacted. In issues like this, scientists have an added responsibility to keep their personal views separate from the science, and to make it clear to others when they diverge from the objectivity they (hopefully) adhere to in their scientific research. I think you have failed to do this.

Your approach of trying to gain scientific credibility for your personal views by asking people to endorse your letter is reprehensible. No scientist who wishes to maintain respect in the community should ever endorse any statement unless they have examined the issue fully themselves. You are asking people to prostitute themselves by doing just this! I fear that some will endorse your letter, in the mistaken belief that you are making a balanced and knowledgeable assessment of the science

-- when, in fact, you are presenting a flawed view that neither accords with IPCC nor with the bulk of the scientific and economic literature on the subject.

Let me remind you of the science. The issue you address is one of the

timing of emissions reductions below BAU. Note that this is not the same as the timing of action -- and note that your letter categorically addresses the former rather than the latter issue. Emissions reduction timing is epitomized by the differences between the Sxxx and WRExxx pathways towards CO2 concentration stabilization. It has been clearly demonstrated in the literature that the mitigation costs of following an Sxxx pathway are up to five times the cost of following an equivalent WRExxx pathway. It has also been shown that there is likely to be an equal or greater cost differential for non-Annex I countries, and that the economic burden in Annex I countries would fall disproportionately on poorer people.

Furthermore, since there has been no credible analysis of the benefits (averted impacts) side of the equation, it is impossible to assess fully the benefits differential between the Sxxx and WRExxx stabilization profiles. Indeed, uncertainties in predicting the regional details of future climate change that would arise from following these pathways, and the even greater uncertainties that attend any assessment of the impacts of such climate changes, preclude any credible assessment of the relative benefits. As shown in the WRE paper (Nature v. 379, pp. 240-243), the differentials at the global-mean level are so small, at most a few tenths of a degree Celsius and a few cm in sea level rise and declining to minuscule amounts as the pathways approach the SAME target, that it is unlikely that an analysis of future climate data could even distinguish between the pathways. Certainly, given the much larger noise at the regional level, and noting that even the absolute changes in many variables at the regional level remain within the noise out to 2030 or later, the two pathways would certainly be indistinguishable at the regional level until well into the 21st century.

The crux of this issue is developing policies for controlling greenhouse gas emissions where the reductions relative to BAU are neither too much, too soon (which could cause serious economic hardship to those who are most vulnerable, poor people and poor countries) nor too little, too late (which could lead to future impacts that would be bad for future generations of the same groups). Our ability to quantify the economic consequences of "too much, too soon" is far better than our ability to quantify the impacts that might arise from "too little, too late" -- to the extent that we cannot even define what this means! You appear to be putting too much weight on the highly uncertain impacts side of the equation. Worse than this, you have not even explained what the issues are. In my judgment, you are behaving in an irresponsible way that does you little credit. Furthermore, you have compounded your sin by actually putting a lie into the mouths of innocents ("after carefully examining the question of timing of emissions reductions, we find the arguments against postponement to be more compelling"). People who endorse your letter will NOT have "carefully examined" the issue.

When scientists color the science with their own PERSONAL views or make categorical statements without presenting the evidence for such statements, they have a clear responsibility to state that that is what

they are doing. You have failed to do so. Indeed, what you are doing is, in my view, a form of dishonesty more subtle but no less egregious than the statements made by the greenhouse skeptics, Michaels, Singer et al. I find this extremely disturbing.

From: Keith Briffa <k.briffa@uea.ac.uk>
To: Stepan, Eugene
Subject: papers/Holocene/etc.
Date: Fri Dec 5 16:12:59 1997
Cc: fritz.schweingruber@wsl.ch

Dear Stepan and Eugene

I don't know whether you have received your copies of the 1996 issue of *Dendrochronologia* yet but in case not I have seen the issue and it looks very good. Your two papers on Yamal and Taimyr are there and they both look excellent. Stepan I received receipt for money and the data and photographs your sent . I am very grateful for all . Thankyou. Again I can only say sorry about the problems of money transfer.

The first thing I wish to say is that I know we have been unsuccessful with our recent applications to INTAS and COPERNICUS . However , if you agree , I would like to resubmit a new proposal to INTAS in March to continue the development of the long chronologies. I will write it and stress the success todate and the need to carry on the formal collaboration. What is your joint opinion on this?

The Nature paper on the decline story is now officially accepted and I still hope it may come out before Christmas or at least shortly afterwards. I will be writing a story about increasing basal area on the long term as I showed in Krasnoyarsk and I also intend to submit this to Science or Nature and you will be coauthors on that. We also have done a lot of work on the growing season degree day reconstructions and will write up another joint paper on this soon - but I am trying to get the ringwidth data produced by you two incorporated with the ringwidth data produced from the density measurements - because Stepan told me these may be longer and anyway they will help the quality of the ringwidth data anyway. You may therefore get some messages or questions from Harry (Ian Harris) who works for me asking about the locations. Please be patient and try to help him with this if necessary.

Unfortunately, next year I have several major meetings to attend and present our joint results. Each of these meetings is very important. In March, I must give a major review paper at the PAGES open Science meeting in London. This must cover all dendro - or at least the best of it - which of course includes our own work! Early next year I will ask for the full data sets as they then stand, for Yamal and Taimyr so that I can try restandardising and calibrating against regional mean climate data. If there are not likely to be more data than I already have , can you let me know. Also in March, I will go to Copenhagen for an European Community meeting of project leaders of projects dealing with Arctic climates. This is the sort of meeting I must attend and put on a good show if we hope to get further funding in 1999 onwards. Later in the year there is a big climate conference here at which I must give a review of dendroclimatic research.

By January , we are supposed to exchange data within the project for possible research - but with the proviso that nothing can be written about work using others data without full collaboration and coauthorship. Are you both willing to let your chronologies as published be released to the rest of the group at that time?

Finally, I have got permission (provided I can find the money to pay for it) to have a special issue of *The Holocene* dedicated to the results (todate) of the ADVANCE-10K project. It will contain a series of

major articles describing each piece of the work and I wish these to include large ,detailed papers on the Yamal and Taimyr chronologies , and perhaps a separate paper on the Northern Urals work. I hope to get a firm committment now from Both of you that you will be prepared to do this. I would be happy to help with specific ideas and some analysis and plotting of all Figures and retyping if you wish. The provisional deadline for the production of the papers would be late summer or autumn at the earliest.

I am of course very keen to continue our collaboration and next year as soon as I know more about the details of the European Community Framework 5 plan (which , incidently now contains a heading 'Global Change') I will be putting together another application. I will try my best to include you both as full partners in this if it is at all possible.

After the Krasnoyarsk meeting I heard nothing about the final decision regarding an application for a Transect Office in Krasnoyarsk (at some time someone had asked me would I coauthor an application) . Has this idea died? Also will there be a proceedings book arising out of the meeting ? Do I have to prepare something?

Eugene, I have a revised version of the paper you gave me to read some time ago about the cell growth model work. Do you intend me to send this to Dendrochronologia or just send the annotated manuscript back to you? I have a question about meaning that held me up and needs your answer - can I fax you something?

Finally , - I wish you each and everyone in your laboratories and all your families the very best christmas and new year .

Keith

Subject: Invitation to the SRES meeting in Berkeley
Date: Tue, 13 Jan 1998 17:50:47 +0100

<x-rich>Dear Colleagues,

I would like to confirm that we will hold the next SRES meeting on 7-8 February

at Lawrence Berkeley National Laboratory in Berkeley, California. Lynn Price is the organizer of the meeting. Below is her contact information.

Ms. Lynn Price

Energy Analysis Program

Lawrence Berkeley National Laboratory

MS 90-4000, 1 Cyclotron Road

Berkeley, CA 94720

U.S.A.

(001-510) 486-6519

(001-510) 486-6996

e-mail: lkprice@lbl.gov

The main purpose of the meeting is to review the work progress of the four

modeling groups that have been involved in first quantifications of the four storylines. My expectation is that we can harmonize various model runs into four initial scenarios. Thus, this will be primarily a modelers'

meeting focusing on technical issues, storyline interpretation and consistency of first quantifications. It will not have the character of a

Lead Authors meeting in the strict sense. It is nevertheless an important

meeting for all modeling groups who have volunteered to quantify storylines, since this work needs to proceed in order for us to meet our original timetable and cannot be postponed until the next Lead Authors' meeting in the spring.

I hope that most of you can attend. Your input would be valuable in this early stage of modeling work. Furthermore, it would be good to also take the opportunity of this meeting to review the so-called zero-order-drafts (ZODs). The deadline for the submission of the final versions of the ZODs is 15 January (Thursday), so I expect that we will also have new material to discuss.

Although I realize that this meeting will take place on rather short notice and not all of you will be able to obtain the necessary approvals and visas to attend, I nonetheless believe that it is important at this stage to hold an informal meeting with the four modeling groups. I have funds available for the four lead authors from developing countries:

Matthew Luhanga, Zhou Dadi, Henryk Gaj, and Emilio La Rovere. As noted above, a more formal meeting of the complete writing team will be held sometime in March or April, at which time I hope everyone will be able to attend.

Please confirm your attendance for the February meeting with me as soon as possible (this week if you can), so that we can reserve sufficient hotel space in Berkeley.

Again, for those of you who are working on Zero Order Drafts, please remember that this Thursday is the deadline for completion. I look forward to receiving these.

Best Regards,

Naki

Naki,

Thanks for the invitation to the SRES meeting.

Given the funds situation at your disposal, I am opting out of attending the meeting. I would however like to offer any assistance on issues concerning developing / Asian countries. Specifically, I have data on structural changes of GDP and energy for countries in Asia-Pacific. The structural transitions in these countries offer interesting insights and directions for scenarios. I have passed an analysis of 12 countries to Tae. The countries include the important economies in Asia-Pacific, namely China, India, Japan, Korea, Indonesia, Malaysia, Thailand, Pakistan, Bangladesh etc. I think the structural changes in developing countries is a very vital aspect for specifying future emissions. Also, well documented and specified information on this shall help the policy exercises later which shall use our emissions scenarios as reference.

I think the modelling groups may also require some inputs (and insights) for handling developing country specifications in the models. In the past we have pointed out several lacunas - such as neglect of traditional biomass, disequilibrium, informal economy, geopolitical realities etc. These also influence technological assumptions and constraints. In fact our scenarios are very well suited to handle some

of these aspects differently. The modellers may have to be advised to handle these aspects suitably. This is vital since we aim to specify the emissions regionally.

An another issue I wish to bring to your attention relates to discount rates. I know your competence on this issue. However, the modelling difficulties (and paradigm itself) often stop us from using different discount rates. The persistence of high discount rates in developing economies is an observed fact. This may not equalize globally during the next half century (or more). Even if we may not want to have different discount rates (since this upsets the underlying neoclassical paradigm), we may just ask the modellers to ensure that the results are not sensitive to this.

A more interesting issue concerning the discount rates for our scenarios is that the different futures (scenarios) would have different associated discount rates. The sustainable development type scenarios (e.g. B1 scenario) may have lower discount rate than our A scenarios. If we run all scenarios with same discount rate, this would be a contradiction. I know there are no easy answers around this since we do not want to confuse the users of scenarios later on with too many different parameters. However it may be worth providing different specifications for important parameters or caveats where we anticipate contradictions.

Given the recent developments in East Asia, it may be worth to take a relook at A1 scenario and consider whether the Tiger World would transit to A1 or A2. This is just an aside.

Wishing you a very happy new year.

Frank

I do not recall what Kyrdianov has worked on - sorry. However, Hantemirov has done outstanding work putting together and as yet preliminarily analysing what wii no doubt become a world famous sub fossil chronology in the Yamal area of northern Siberia. Indeed I will feature this work in my presentation.

Frank, an important point requiring your instant help! Some time ago I got a request to write something for a NERC(?) publication related to my talk in April. Now I can't find it and desperately need to contact the guy about length and deadline - which may have passed. Can you help? I know you coordinated with him.

Yes I know I'm a _anker!

Keith

From: GERNER THOMSEN <gerner@get2net.dk>
To: Keith Briffa <k.briffa@uea.ac.uk>
Subject: Ph.D. in Sweden
Date: Mon, 19 Jan 1998 06:15:55 +0100
Reply-to: gerner <gerner@get2net.dk>

Dear Keith!

I contacted Hakan Grudd last week. He is also positive about a Ph.D. for me in Stockholm.

I have tried to make a formulation of a project. Please, read it and let me know what you think. Maybe the project is overlapping with that of Grudd or maybe you have better ideas. It could also be that I have misunderstood some points.

I have sent the project formulation to Schweingruber, Grudd and Kalen. I send it to Schweingruber because I already contacted him last week (before I got the message from you). He is also interested in the project and anyway he will get involved if I am going to train in Birmensdorf.

Best regards from:

Gerner Thomsen

Description of project

1. Background

Dendroclimatology can be defined as the use of tree rings to study and reconstruct past and present climate (Kaennel & Schweingruber, 1995). Global average surface temperatures have risen by 0.3-0.6 °C since the middle of the 19th century (Folland et al., 1990). Climatologists seek to establish the extent to which this rise may be attributable to an enhanced greenhouse effect and so need to distinguish anthropogenic from 'natural' climate fluctuations (those that would occur without anthropogenic influences) to help them make predictions of future climate changes (Briffa et al., 1996a). Clearly the century-long instrumental record is not long enough to accomplish this. Paleoclimatic fluctuations older than meteorological measurements can be inferred from a variety of data sources, including tree rings, records of vegetation processes (e.g. pollen in lake

sediments), records of ice layer in ice cores, historical records, etc. (Eddy, 1992). However, within a time frame of the last two millennia dendroclimatology has shown to be the most powerful tool available to provide globally distributed, annually resolved paleoenvironmental records (Luckman, 1996). The growing influence of dendroclimatology in paleoenvironmental studies can be seen in the fact that almost a third of Bradley and Jones' volume *Climate since AD 1500* (Bradley & Jones, 1992) deals with dendrochronology and dendroclimatic reconstruction.

Near the polar and altitudinal tree lines, tree growth is mainly dependent on summer temperature. As northern latitudes are regarded as being strongly affected by global climate changes, a network of chronologies is established along the polar tree-line in Eurasia (Briffa et al., 1996b). At specific locations in these northern high-latitude regions it is possible to extend the tree-growth record back beyond the life span of living trees by amalgamating the measurements from overlapping, absolutely-dated series of measurements made on dead wood from historical or archeological provenances or naturally surviving above ground, in peat or alluvial sediments, or preserved in lakes. The first pair of (ring-width and density) chronologies, made up from samples of Scots pine (*Pinus sylvestris* L.) at several locations adjacent to Lake Torneträsk, northern Sweden, have been used to reconstruct summer (April-August) temperatures representing a large region of northern Fennoscandia from AD 500 to 1980 (Briffa et al., 1990, 1992). The Fennoscandian temperature records show that marked high-frequency (interannual-to-century) timescale variability together with marked long-timescale (multicentury) variations in summer temperatures have been a characteristic feature in this region during the last millennium. Similar data from samples of larch (*Larix sibirica*) on the eastern slopes of the northern Urals have been used to reconstruct regional summer (May-September) temperatures representing a region of north-western Siberia for the period 914 to 1990 (Briffa et al., 1995b). As a part of developing the north Eurasian chronology network, two projects currently underway aim to build continuous multimillennial pine ring-width chronologies in northern Sweden and Finland, spanning 7000-8000 years (Briffa et al., 1995a). In Russia a similar project underway aim to build larch ring-width chronologies in Yamal Peninsula, also spanning 7000-8000 years (Shiyatov, 1997).

The application of radiodensitometry in the analysis of conifer rings throughout Europe (Schweingruber, 1985) show the considerable amount of additional information lying in density, as compared with total ring width. Obviously, external factors have a more uniform influence on cell wall growth in latewood (density) than on cambial activity (ring-widths). In trees of the northern and subalpine timberlines, maximum latewood density is essentially a measure of mean summer temperature (ibid.).

2. Purpose of this study

2.1. Main objective

The main objective of this study is to provide additional information for a more precise climate reconstruction based on the already existing Torneträsk-chronology in northern Sweden (AD 500 to 1980) and a future supra-long chronology (BC 7000 to 1996), based on ring-widths and maximum latewood density of Scots pine (*Pinus sylvestris* L.) from the same area.

2.2. Elaboration of the main objective

One of the most fundamental underlying principles in dendroclimatology is the assumption of uniformitarianism in the response of data to climate forcing. The uniformitarian principle implies that "the physical and biological processes which link today's climate with today's variations in tree growth must have been in operation in the past" (Fritts, 1976). However, it is a moot point whether the assumption of uniformitarianism holds when past climate variations are inferred from long chronologies. The problem arises because the extrapolation always is based on a regression model calibrated on very short meteorological records. Long chronologies, as those seen in northern Scandinavia and Siberia, are made up from trees of different ages growing under more or less uniform conditions. In such chronologies there must always be uncertainty regarding the long-term stability of (non-climate) environmental influences or differing climate sensitivity due to the inhomogeneity in the sampled material (Briffa, 1995a, Briffa et al., 1996a). The climate signals in chronologies may, to some extent, be affected by:

1.
Inhomogeneity in the site characteristics of the samples (soil fertility, water holding capacity of the soil, altitude, exposure of slope, etc.)
2.
Inhomogeneity in series length of samples (tree age)
3.
Inhomogeneity in tree growth form and population density of samples
4.
Anthropogenic influence (nitrogen deposition, raise in CO₂ level) producing enhanced tree growth in the recent part of the chronology

5. Series replication in the chronology

6. The technique used to remove the non-climatic, age-related bias in individual series (a technique known as standardization in dendroclimatology)

This study will focus on the influence of point 1-3 on the climate signal seen in densities of Scots pine from the area of Torneträsk in northern Sweden. It is well-known that the Torneträsk-chronology is subject to the inhomogeneity in samples described in point 1-3, but it is not clear to what extension these inhomogeneities affect the climate signal in the chronology. Thus, a study of the influence of inhomogeneity in the samples will provide valuable additional information for a more precise interpretation of the summer-temperature record inferred from the already existing Torneträsk-chronology. In the same way it will highly increase the value and confidence of climate reconstructions from future supra-long pine-chronologies in this region. The growth parameter under investigation is maximum latewood density. In this way the study will complement an ongoing similar study on ring-widths of Scots pine from the same region (Grudd, 1998).

2.3. Partial objectives of the study and publications

Methodologically, the project can be divided into three, but overlapping stages:

1. Building of density pine-chronologies around Torneträsk from different sites. Various site conditions (mainly soil fertility, water holding capacity of the soil, altitude, and tree population density) and different age classes must be taken into consideration. No less than 10-12 chronologies must be estimated.

2. Analysis of climate-growth relationships of the pine-chronologies, focusing on differences between high-frequency and low-frequency variability in the climate data. The results are compared and conclusions are drawn about the diversity of climate signal seen in density-chronologies from Scots pine growing under various conditions in the area around Torneträsk.

3.

Re-interpretation of the already existing Torneträsk-chronology on the basis of the new information provided by the study in case and the ongoing similar study of ring-widths from the same region (Grudd, 1998)

The results are published in three articles with the following provisional titles:

a)

"Site-induced differences in climate-growth response of *Pinus sylvestris* L." (The article focuses on differences in climate-growth response for trees growing on different soil types and for trees from stands with different population density)

b)

"Altitude and age as parameters of climate-growth response in *Pinus sylvestris* L." (The article focuses on differences in climate-growth response for trees growing at different altitudes and trees in different age-classes)

c)

"Possible site-induced changes in the climate-growth response of the 1,400 year tree-ring chronology from northern Fennoscandia" (A re-interpretation of the existing Torneträsk-chronology is made on the basis of the new information)

3. Methods

3.1. Sampling strategy

3.1.1. Selection of sites and stands

As already pointed out, various site conditions and different age classes must be taken into consideration. Site homogeneity largely determines the quality of the chronology. That is, the factor under investigation which is assumed to affect the climate-growth response must be constant all over the site, and other possible affecting factors are minimised. It is important that the stand have not been similarly damaged by fires, wind, or other catastrophic factors to extract reliable climatic information. Site characteristics will be noted (topography/geomorphology, soil conditions, vegetation description, signs of human impact, etc.).

3.1.2. Selection of trees

Trees should be in a dominant position (with the possible exception of stand density studies), without irregular growth which probably disturb the climate signal in the tree-rings. Individual variability in the final chronology decreases with an increasing number of samples. Consequently, two cores from at least 12 living trees are necessary to obtain a site-chronology of sufficient quality. It is best to sample a few more trees than necessary so that anomalous cores may be discarded. Trees of different age classes will be cored to allow for systematical studies on age-related bias in the climate-growth response.

Samples are taken at breast height with an increment borer. The cores are stored in air-dry conditions after labelling with a pencil. Growth irregularities (compression wood, wound tissue, etc.) are excluded by avoiding sampling in the vicinity of wound and of upslope and downslope sides of trees growing on sloping ground. Cores are taken as nearly perpendicular to the fibre orientation as possible. This can greatly reduce the variability owing to technical processing in densitometric studies (Schweingruber et al., 1990). Core characteristics will be noted (tree height, stem diameter at breast height, crown size and condition, injuries and irregular growth, coring direction and height, etc.). Sites and trees will be documented photographically.

3.2. Sample preparation, measurement, and chronology building

3.2.1. Preparation

Resins and heartwood substances must be chemically removed as they will influence on the X-ray absorption (Schweingruber, 1990). This is done through distillation in Soxhlett device; resins are extracted with alcohol, heartwood substances with water. After removal of resins and heartwood substances, laths of equal thickness have to be cut from the round cores. The Birmensdorf system may be used where the core is glued to a wooden support with the radial surface uppermost and a 1.25-mm-thick lath cut out with a small twin-bladed circular saw. To obtain comparable density values, the moisture content of the wood must be kept constant.

3.2.2. Measurement of density

The irradiation of film can be done with different methods. Two methods, which have proved to be useful are:

1.

Irradiation of a film (Kodak, Type R, single-coated industrial X-ray film)

resting on the moving stage. The film is transported at five cm/min under the radiation source, which is 31 cm above, and irradiated at 20kVh and 2mA (Vancouver system)

2.

Irradiation of a film (Kodak, Type X-Omat TL, double coated medical X-ray film) resting on a stationary stage at 11 kVh and 20 mA for 90 min. The source is 250 cm above the film (Nancy system)

The film is developed and the different gray levels produced on the radiograph by the wood samples are converted to wood density values. The basic instrument used is the densitometer (ibid). Analog or digital processing of the actual measurements produces a density profile from which the desired parameter (maximum density) is registered.

3.2.3. Dating and chronology building

For dating, chronology building and quality control, the program COFECHA (Holmes et al., 1986) may be used. In addition a manual dating control has to be done at the light table or monitor, comparing each curve with an existing master chronology. The procedure ensures precise dating of every tree ring.

3.3. Data processing

3.3.1. Standardization of tree-ring data

Before averaging tree-ring curves to mean chronologies which shall be used for dendroclimatological purposes, the raw values must be standardized to index values. In the same process, one has to remove the natural age trend of trees and eventual density variations caused by stand dynamics, and not representing climate. Also in this process, it is crucial to control the effect of detrending at the light table or on the monitor, comparing the original with the detrended curve. Much depends from this process, as the dendrochronologist here decides which portion of low frequency variation that is removed from the series. This in turn affects climate information inferred from the chronology. Therefore, several detrending methods have to be tested in this study.

3.3.2. Computing climate-growth response

Climate-growth models will be computed for all individual chronologies. The period selected for climate-growth modelling, is the period for which

climate data are available (the earliest series start in AD ??). Different techniques are existing for estimation of the climate-growth response. For example, simple correlation analysis may be used or a regression-technique based on principal component analysis. It may be relevant to detect non-linear relationships between climate variables and ring growth, as well as to study single years with special tree-ring (pointer years) and climate events. To detect changes in climate-response over time the Kalman filter can be used.

4. Time schedule

The project will be performed during three years (June 1998 to June 2001). The Ph.D. student will follow courses corresponding to 40 weeks of studies. >From earlier working, the following assumptions regarding time consume for field work and measuring can be made: It can take a number of days to become familiar with the localities and to find the most suitable pine stands. At each site, one to two days are needed for sampling and site description, provided that the pines do not stand too scattered, and long walking distances can be avoided. Time for measuring and chronology building should be estimated rather high (2-3 weeks per site).

1998:

Summer:

Preparing of a detailed sampling strategy for the whole project (2 weeks) and field work (6 weeks). The field work will focus on sampling of trees from about six sites with varying conditions (soil fertility and water holding capacity).

Autumn semester:

Training in use of densitometry equipment at the institute of Forest, Snow and Landscape in Birmensdorf, Switzerland. Measurement of samples collected in the summer.

1999:

Spring semester:

Continued measuring of samples at the university in Stockholm. Systematical analysis of standardization methods and construction of six site chronologies. Start of analysing climate-growth response in chronologies.

Summer:

Field work (6 weeks) which will put focus on sampling trees from about six sites in different altitudes and with different stand densities.

Autumn semester:

Measuring of the summer's material at the university in Stockholm.

Systematical analysis of standardization methods and construction of six new site chronologies. Analysing climate-growth response in chronologies.

2000:

Spring semester:

Analysing climate-growth response in all chronologies. Preparation of publication (a).

Autumn semester:

Analysing age-related climate-response. Preparation of publication (b).

Comparison of results with similar study on ring-widths (Grudd, 1998).

2001:

Spring semester:

Last statistics, preparation of publication (c), preparation of disputation.

Hi everyone,

I need to have a firm number of attendees by the end of the day tomorrow (Wednesday January 21st) in order to hold rooms at the hotel. At the end of this e-mail I have listed the information that I currently have regarding who is planning to attend, who is not planning to attend, and who has not responded.

I will hold a room for each of the people listed below as attending unless I hear otherwise from you.

If you are in the list of people who have not yet responded and you plan to attend, please let me know ASAP.

If I have not heard from you by the end of the day tomorrow I will assume that you will make your own arrangements for accommodations.

For those of you who want me to hold a room for you, I will send information on how to make your reservations in a day or so.

Thanks,

Lynn

Reply-to: Tom Wigley <wigley@meeker.ucar.edu>
Cc: hm_pitcher@pnl.gov, o.brown@uea.ac.uk

Mike,

Thanks for the quick response. Responses to responses follows....

(1) I tried the composite GHG plus UIUC SUL on Norm's machine, in just the way you said. However, the results for the USA seem to be identical to those using **only** UIUC GHG input. I'll try again.

(2) You are right in saying one shouldn't scale GHG patterns by GHG+SUL dTs. However, to be strictly consistent one should never allow GHG patterns to be used alone. So you are **not** being consistent if you allow this---which you do. The point then is to minimize the extent of the inconsistency.

It is unarguably correct that the global-mean temperature to use is the one containing all forcings (i.e., column 6 in **DRIVE.OUT**). The choice then is what pattern(s) to use. If we had no SUL information, we would have to use GHG patterns; as in the original SCENGEN. Scaling these with the MAGICC GHG output would give both incorrect patterns and incorrect global-mean warming. Scaling with column 6 at least gets the global-mean warming correct (within MAGICC uncertainties). You seem to have chosen to get **both** things wrong, instead of just the patterns.

I can see some logic in your method; I just think (strongly) that it is wrong. At the very least, it will be confusing to the user. If the user selects only GHG model patterns, then won't they wonder why the global-mean temperature is inconsistent with MAGICC? To take an extreme case, suppose the full dT is 2degC and the GHG-alone dT is 3degC. Is it better to scale an approximate pattern (i.e., the GHG pattern) by 2degC or 3degC? In my view, GHG scaled by 2degC would be much closer to GHG+SUL scaled by 2degC than GHG scaled by 3degC. Surely the real issue (given that it is impossible to be entirely consistent in this case) is to get a result that is as close to the 'right' result as possible. I feel quite sure that scaling by column 6 is best on this basis---especially given that the patterns are much more uncertain than the global-means. I

think this is absolutely beyond doubt.

The bottom line here is that consistency is impossible if one uses only GHG patterns. Column 6 was included deliberately, and after some thought (along the lines noted above).

Of course, it is possible to get column 6 results by adding columns 2, 3, 4 and 5 as they now stand (and as they are in the version that you have). However, one cannot do this with the correct *raw* column 3, 4, and 5 output because of the nonlinear direct forcing effect. It just happens that, in your version, I 'faked up' column 5 as the difference between column 6 and the sum of columns 2, 3 and 4. I did this simply to get the code working; but (as you now know) I never got around to fixing it up until now. In the latest version, column 6 is again equal to the sum of columns 2, 3, 4 and 5 because I scale columns 3, 4 and 5 to ensure that this is so.

(3) Re HadCM2, again it is impossible to be consistent. What I said before is that the reason for adding these results is simply to make them readily available. I do *not* advocate using them in combination with any other model results. It is, I believe, perfectly reasonable to scale these results with column 6 data. Of course, this 'hides' an assumption about the relative magnitudes of the GHG and SUL components---i.e., it assumes that the HadCM2 relative magnitudes are okay. The point of scaling, however, is to account for other factors that change the global-mean temperature relative to HadCM2 results, such as different sensitivities.

I agree with you that it would not be an efficient use of time splitting the HadCM2 SUL results into GHG and 'aerosol' component patterns. The whole point of the sulphate part of SCENGEN is to look at the influence of different SO2 emissions patterns. Splitting up HadCM2 wouldn't help here at all.

I also think it would be valueless to hardwire HadCM2 dT results into SCENGEN---again, this would defeat the purpose of including these results. It would introduce an additional inconsistency; since HadCM2 patterns change with time, it would not be logical to scale the 2071-2100 pattern with (e.g.) 2031-2060 dT. Of course, you could argue that it is illogical to scale this pattern with (e.g.) 2031-60 dT from MAGICC; but this is a different issue that I don't think is worth discussing at this time.

(4) Thanks for explaining the UIUC 'other data' problem. I will ask Michael whether he can provide full global fields for the other variables, since it really would be valuable to include them. If he can give us these data, could you add them to SCENGEN? (re this, see below)

(5) I appreciate your problems with Olga and Mike Salmon. As far as I can see, incorporating the revised MAG.FOR code into MAGICC/SCENGEN shouldn't be too difficult. I can, however, get hold of some money to pay for some of Mike's time to do other work---perhaps \$5000 or so. Can we set something up? The contractual side would be easy---just a matter of agreeing a brief statement of work, and having CRU send a bill. If this is useful and possible, then can you check it out with Mike and Trevor?

Cheers,
Tom

Subject: minutes of the SRES informal modelers' meeting
Date: Mon, 16 Feb 1998 16:48:49 +0100
Cc: kuszko@uea.ac.uk, naki@uea.ac.uk

Dear Colleagues,

Please find attached the minutes of the SRES informal modelers' meeting, 7-8 February 1998 in Berkeley, California. I would like to thank those who participated in the meeting and Lynn Price in particular, both for the excellent organization of the meeting and for drafting the minutes. Please note the deadlines detailed in our work plan; for those of you completing the next two rounds on model runs and storylines, this will be especially important. Additional submissions to the SRES scenario database would be also greatly appreciated. Finally, if anyone would like to receive a hard copy of the materials we discussed in Berkeley, please contact Anne Johnson at johnson@iiasa.ac.at. (The same material was sent to you by e-mail on January 30).

With best regards,

Naki

Dear Mike,

What is the current state of play regarding definition of improved sulphur emission scenarios? I have the 'zero-order draft' by Arnulf Grubler that you sent me at the beginning of November, as well as a shorter note by Hugh Pitcher. Have there been more developments since then?

As you can probably guess, this enquiry results from Geoff Jenkins's visit to Brussels (?) a few days ago. Geoff is now keen that we should use better emission scenarios than IS92a and is pressing me for action, even if this means using an interim scenario that has not yet been agreed by IPCC.

Best regards,
David

Subject: Next SRES Meeting, week of 27 April in Washington
Date: Tue, 24 Feb 1998 19:01:16 +0100

Dear Colleagues,

I am writing to let you know that the next IPCC-SRES Full Authors meeting will be held the week of 27 April 1998 (instead the week of 6 April) in Washington, D.C. Bob Watson of the IPCC will attend. The exact dates during that week are not yet fixed, but I expect that we will have a full authors meeting for two days, preceded by a two-day modelers meeting. Please let me know soon--today if possible--whether you will be available during this week; it is critical that we finalize the dates early so there will be sufficient time to ensure funding for our colleagues from developing countries who need IPCC support.

I look forward to hearing from you very soon.

Best regards,

Naki

Prof. Dr. Nebojsa Nakicenovic

Project Leader

Environmentally Compatible Energy Strategies

Dear Prof. Krenke

I am happy to submit the proposal from here or to be associated with it in collaboration with our ongoing tree-ring development work (with Fritz Schweingruber, Eugene Vaganov and Stepan Shiyatov) but you will have to take the initiative in writing and organising the proposal. I am very tied up with meetings and I have to write and submit another INTAS proposal with the people I mentioned to continue development and analysis of the long chronologies at Yamal and Taimyr. The others need not be listed if you do not wish but I would ask you to discuss with Prof. Vaganov how he sees this being balanced with his priorities and our ongoing work. We will use our own transfer function approach (in our ADVANCE European project) to reconstruct circulation in summer based only on the tree-ring data but this is no worry for you. If you can get the draft to me soon - with details of all participants and money I will then look at it and revise and submit as you wish.If this is to happen you must take the initiative of putting it together.

please let me know what you intend
as soon as possible. I am here only for one more week!

Keith

Subject: Tentative Attendance of IPCC SRES Meeting, 27-30 April 1998
Date: Fri, 27 Feb 1998 15:30:22 +0100

Dear Colleagues,

Thank you for your prompt response to my recent e-mail message regarding
the next IPCC SRES meeting. I am glad to hear that so many of you will
be
able to attend, since this will be a very important discussion. The plan
is
to hold the modelers' meeting on April 27 and 28, followed by the full
authors' meeting on April 29 and 30.

Below is a list of those who are planning to attend:

Joseph Alcamo <alcamo@usf.uni-kassel.de>
Dennis Anderson <dennis.anderson@ic.ac.uk>
Zhou Dadi <becon@public3.bta.net.cn>
Gerald Davis <Ged.R.Davis@si.simis.com> (part of the meeting)
Bert de Vries <Bert.de.Vries@rivm.nl>
Jae Edmonds <ja_edmonds@pnl.gov>
Joerg Fenhann <j.fenhann@risoe.dk>
Stuart Gaffin <stuart@edf.org>
Henryk Gaj <Fewewar@tarnet.pl>
Kenneth Gregory <kennethgregory@msn.com>
Arnulf Gruebler <gruebler@iiasa.ac.at>
Erik Haites <ehaites@netcom.ca>

Michael Hulme <m.hulme@uea.ac.uk>
Tae-Yong Jung <tyjung@his.keei.re.kr>
Mathew Luhanga <vc@admin.udsm.ac.tz>
Julio Torres Martinez <dpid@[169.158.128.138]>
Laurie Michaelis <laurie.michaelis@oecd.org> (part of the meeting)
Tsuneyuke Morita <t-morita@nies.go.jp>
Richard Moss <rmos@usgcrp.gov>
Nebojsa Nakicenovic <Naki@IIASA.ac.at>
Youssef Nassef <nassef@hotmail.com>
Hugh Pitcher <hm_pitcher@pnl.gov>
Lynn Price <lkprice@lbl.gov>
Holger Rogner <rogner@iiasa.ac.at> (strong possibility)
Priyadarshi Shukla <shukla@iimahd.ernet.in>
Leena Srivastava <leena@teri.res.in>
Robert Swart <rob.swart@rivm.nl> (strong possibility)
Ernst Worrell <e.worrell@nwsmail.chem.ruu.nl>

I will be in touch with additional details in the coming weeks.

Best regards,

Naki

Dear Colleagues:

Naki has asked me to send you the attached IPCC Zero Order Draft by
Dennis
Anderson on the influence of social and economic policies on future
carbon
emissions. It is an updated version of the ZOD presented at the Berkeley
SRES meeting. The attachment is missing the last three charts, but these
will be available in time for the Washington, D.C. meeting. If you have
any comments, please send them directly to Dennis Anderson:

Dennis.Anderson@Economics.oxford.ac.uk

I have attached the ZOD in both rich text and MS Word formats.

Regards,

Anne Johnson

Dear Keith,

I am in Birmensdorf now and will stay here until March 20s.
As far as I know Stepan Shiyatov has to translate the proposal into Russian because of this year there are two possibility to get grant. The one is just INTAS competition and other is joint INTAS-RFBR (Russian Foundation for Basic Researches) ones with the same requirements and grant amounts. For second one we have to submit russian version to RFBR. If proposal will reject by RFBR it will be automatically submit for INTAS competition.

Attached file is the ring-width series of subfossil (first letter is L in series number) and living larches from Yamal, used for mean chronology developing (best or the only ones for corresponding period).

Best regards,
hope to see you in London next month,

Rashit Hantemirov

6. Regional Stewardship (B2)
7. Scenario comparisons
8. Conclusions

Appendix 1: Scenario quantification

1. Introduction

The IS99 scenarios have been constructed to explore future developments in the global environment with special reference to the production of GHGs.

These scenarios are being developed in three phases:

- Phase 1: the Special Report on Emissions Scenarios (SRES) team is preparing a set of scenarios for wide public discussion, which is the subject of this note,
- Phase 2: the scenarios will be placed on the World Wide Web, subject to public scrutiny, and suggestions for relevant modification of the scenarios will be sought,

- Phase 3: the scenarios will be finalised for peer review, incorporating suggestions received during the public review, by April 1999.

Phase 1 centred on a facilitated open process for Lead Authors at workshops

in Paris, Vienna and Utrecht. The scenarios developed allow for a broad range of GHG emissions and provide a basis for reflection on policy.

- 1.1 What are scenarios?

Scenarios are pertinent, plausible, alternative futures. Their pertinence, in this case, is derived from the need for climate change modelers to have a basis for assessing the implications of future possible paths for Greenhouse Gas Emissions (GHGs). Their plausibility is tested by peer review, in an open process, which includes their publication on the World Wide Web.

There are clearly an infinite number of possible alternative futures to explore. We have consciously applied the principle of Occam's Razor, seeking the minimum number of scenarios to provide an adequate basis for climate modelling and challenge to policy makers. The alternative futures constructed are not, and cannot be, value free since like any work they self-evidently reflect the team's view of the possible. The scenarios should not be construed as being desirable or undesirable in their own right and have been built as descriptions of possible, rather than preferred, developments. There can be no objective assessment of the probability of the scenarios, although in the prevailing zeitgeist some will appear to individuals to be more likely than others. Scenarios are built to clarify ignorance rather than present knowledge -- the one thing we can be sure of is that the future will be very different from any of those we describe!

2. Scenarios - overview

2.1 Scenarios: key questions and dimensions

Developing scenarios for a period of one hundred years is a relatively new field. Within that period we might expect two major technological discontinuities, a major shift in societal values and a change in the balance of geopolitical power. A particular difficulty is that people are not trained to think in these time-spans, are educated in narrow disciplines and our ability to model large-systems, at the global level, is still in its infancy. Additionally, most databases do not go back much further than 50 years and many less than that. How best to integrate demography, politico-economic, societal and technological knowledge with our understanding of ecological systems? Scenarios can be used as an integration tool, allowing an equal role for intuition, analysis and synthesis.

Terminology

Storylines, Scenarios and Scenario Families

Storyline: a narrative description of a scenario (or a family of scenarios), highlighting the main scenario characteristics, relationships between key driving forces and the dynamics of the scenarios.

Scenario: projections of a potential future, based on a clear logic and a quantified storyline.

Scenario family: one or more scenarios which have the same demographic, politico-societal, economic and technological storyline.

Scenario Classification

Our approach has been to develop a set of four "scenario families". The storylines of each of these scenario families describes a demographic, politico-economic, societal and technological future. Within each family one or more scenarios explore global energy industry and other developments and their implications for Greenhouse Gas Emissions and other pollutants. These are a starting point for climate impact modelling.

The scenarios we have built explore two main questions for the 21st century, neither of which we know the answer to:

- Can adequate governance -- institutions and agreements -- be put in place

to manage global problems?

- Will society's values focus more on enhancing material wealth or be more

broadly balanced, incorporating environmental health and social well-being.

The way we answer these questions leads to four families of scenarios:

- Golden Economic Age (A1): a century of expanded economic prosperity with

the emergence of global governance

- Sustainable Development (B1): in which global agreements and institutions, underpinned by a value shift, encourages the integration of ecological and economic goals

- Divided World (A2): difficulty in resolving global issues leads to a world of autarkic regions

- Regional Stewardship (B2): in the face of weak global governance there is

a focus on managing regional/local ecological and equity

Within these scenario families we examine plausible energy industry and other developments which will contribute to GHG emissions. Although the storylines cannot have explicit climate change policy measures in them there are examples of indirect mitigation measures in some of the scenarios.

The scenario quantifications of the main indicators related to growth of population and economy, the characteristics of the energy system and the associated greenhouse gas emissions all fall within the range of prior studies .

3. Golden Economic Age (A1)

This scenario family entitled "Golden Economic Age", describes rapid and successful economic development. The primary drivers for economic growth and development "catch up" are the strong human desire for prosperity, high

human capital (education), innovation, technology diffusion, and free trade.

The logic of successful development assumes smooth growth with no major

political discontinuities or catastrophic events. The scenario family's development model is based on the most successful historical examples of economic growth, i.e., on the development path of the now affluent OECD economies. Historical analogies of successful economic "catching up" can be found in the Scandinavian countries, Austria, Japan, and South Korea. "Intangible" assets (human capital, stable political climate) take precedence over "tangible" assets (capital, resource, and technology availability) in providing the conditions for a take-off into accelerated rates of development. Once these conditions are met, free trade enables each region to access knowledge, technology, and capital to best deploy its respective comparative economic and human resource advantages. Institutional frameworks are able to successfully sustain economic growth and also to handle the inevitable volatility that rapid economic growth entails.

The "intangible" prerequisites for accelerated rates of economic growth also offer long-term development perspectives for regions that are poorly endowed with resources or where current economic prospects are not auspicious, such as Sub-Saharan Africa. There, for instance, fostered regional trade and capital availability enhance the pull-effects of a strong South African economy. In other regions, growth may be fuelled by domestic know-how and high human capital valued at the international market. An example of this is the thriving software industry of the Indian subcontinent. In yet other regions, growth could be stimulated by the expansion of regional economic partnerships and free trade arrangements (e.g., extensions of NAFTA and the European Union).

The main difference with the historical OECD experience is a certain acceleration in time and space, (i.e., "leapfrogging") made possible by better access to knowledge and technology, a consequence of the high-tech and free trade characteristics of development. Successful catching up becomes pervasive; all parts of the "developing world" participate, though with differences in timing. The final outcome is that practically all parts of the world achieve high levels of affluence by the end of the 21st century, even if disparities will not have disappeared entirely. The current distinction between "developed" and "developing" countries will in any case no longer be appropriate.

As in the past, high growth (a "growing cake") eases distributional conflicts. Everyone reaps the benefits of rapid growth, rising incomes, improved access to services, and rising standards of living. The economic imperatives of markets, free trade, and technology diffusion (i.e., competition) that underlie the high growth rates provide for efficient allocation of resources. Efficiency and high productivity are the positive by-products of the highly competitive nature of the economy. They also provide the economic resources for distributive and social measures required for a stable social and political climate, vital for sustaining high growth rates in human capital, productivity, innovation, and hence

economic growth.

The economic development focus explains its central metric: the degree of economic development as reflected in per capita income levels (GDP at market exchange rates as well as at purchasing power parity rates). The principal driver is the desire for prosperity, all major driving forces are closely linked to prosperity levels, with actual causality links going in both directions. For example, demographic variables co-evolve with prosperity: mortality declines (i.e. life expectancy increases) as a function of higher incomes (better diets and affordable medical treatment).

In turn, changes in the social values underlying the fertility transition also pave the way for greater access to education, modernisation of economic structures, and market orientation. These are key for innovating and diffusing the best practice technologies underlying the high productivity, and hence economic growth, of the scenario.

3.1 Key Scenario Drivers and their Relationships

3.11 Population and Economic Development

High education, stable social relations, and incentives for innovation and

experimentation are the preconditions for productivity increases underlying

rapid economic development in this world-- as a result, social, economic, and demographic development are highly correlated .

The link between demographic and economic variables in the scenario corresponds to present empirical observations: the affluent live long and have few children. High per capita incomes are thus associated with both low mortality and low fertility. Together, this results in rather low population growth, characterised in addition by a considerable "greying" of

the population.

This family of scenarios combines high life expectancy with low fertility,

where OECD rates are assumed to stabilize at current (below replacement) levels, and developing countries follow a similar transition by the mid-21st century. Fertility rates range between 1.3 to 1.7 children per woman. Life expectancy can approach some 95 years, with a regional variation between 80 and 95 years. Global population grows to some 9 billion by 2050, and declines to 7 billion by 2100, the result of continued

below replacement fertility in all regions.

Population ageing results in economic growth rates somewhat lower than historical experience, especially in the OECD countries. Economic growth rates slow over time in proportion to the reduction of the potentially economic active population (age 15 to 65), which decline in some regions to

50 percent compared to the historical average of approximately 70 percent.

For "developing countries", economic growth is based on the most successful cases of economic "catch up" found in history. The economic growth profile of Japan after WW II served as a model to delineate the upper bounds of possible GDP growth for all regions. Consistent with growth theory, GDP expansion initially accelerates, passes through a peak, in which growth rates around 10 percent per year can be sustained for several decades, and then declines. Once the economic and industrial base is firmly established and the economy matures, growth rates decline with increasing income levels. This reflects saturation effects and a higher emphasis on quality rather than quantity at high income levels. The global economy in the "Golden Economic Age" expands at an average annual rate of three percent per year to 2100. This is about the same rate as the global average since 1850 and in this respect may simply be considered "dynamics as usual". Non-Annex-I economies expand with an average annual growth rate of four percent per year, twice the rate of Annex-I economies. By approximately 2030 Non-Annex-I GDP surpasses that of the Annex-I economies. Per capita income disparities are reduced, but differences between regions are not entirely eliminated. Non-Annex-I per capita income reaches the 1990 Annex-I level (14,000 \$/capita) by around 2040. By 2100 per capita income would approach 100,000 \$/capita in Annex-I countries and 70,000 \$/capita in Non-Annex-I countries.

3.12 Equity

Equity issues are not a major concern in the world, but is rather a by-product of the high rates of economic development. Existing per capita income gaps between regions close up in a similar way as between Western Europe and Japan compared to the US in the 20th century. Disparities continue to persist between regions, but more so within particular regions. Nevertheless, the high economic growth rates require a certain degree of income distribution. Extreme income disparities are found to be negative influencing factors for economic growth. Additionally, fair income distribution only assures the large consumer markets and the social cohesion and stability required for the realisation of high economic growth.

3.13 Settlement patterns/communication

Communication technologies and styles are highly homogeneous and extremely developed -- rather than a "global village" future, this is one of "global cities." Existing trends towards urbanisation continue, as cities provide the highest "network externalities" for the educational and R&D-intensive

economic development pattern underlying the scenario. Regional differences in settlement patterns persist. They range from fragmented, compact, but large (i.e., 20+ million inhabitants) cities that depopulate their respective rural hinterlands in Latin America to urban "corridors" connected by high capacity communication and transport networks (in Asia). Regional transport networks include high speed trains and maglevs, which ultimately fuse short- and long-distance transport means into single interconnected infrastructures. In some parts of the world high-tech cars take the place that high-tech trains occupy in other parts. The large urban agglomerates and the high transport demands of a high material growth economy generate vast congestion constraints. These are solved by applying market-based instruments (prices) rather than regulation. Economic instruments include access and parking fees, auctioning off the limited number of new car and truck licenses in megacities, much along the lines of the current stringent Singapore model. Therefore, even at very high income levels, car ownership rates could be comparatively low in parts of the world. In extremely densely populated areas, cars remain a luxury rather than a means of mass transport (viz. Hong Kong). In areas with lower population density, car densities are high (+1 car per inhabitant). Car fuels could be either oil, synfuels, electricity, or hydrogen. Intercontinental transport is provided by energy- and GHG-intensive hypersonic aircraft fuelled by methane or hydrogen. They are the physical transport equivalent of the high capacity virtual communication links of a truly global economy.

3.14 Environmental Concerns/Ecological resilience

Ecological resilience is assumed to be high. In and of themselves, ecological concerns receive a low priority. Instead, the valuation of environmental amenities is strictly in economic terms, e.g., a function of affluence. Non-congestion, clean water and air, and recreational possibilities in nature all assume increasing importance with rising affluence, although preferences for environmental amenities may differ across regions and income levels. For instance, urban air quality and human health are valued highly even at income levels lower than those prevailing in England, where stringent air quality measures were introduced after the "killer smog" of 1952. Reduced particulate and sulphur air pollution become a matter of major consumer preference at levels of \$2,000 - 3,000/capita income in Asia. Altogether, the concept of environmental quality changes from "conservation" of nature to active "management" -- and marketing-- of natural and environmental amenities and services.

3.2 Scenarios

The core bifurcation (with respect to GHG emissions) of the scenario family

unfolds around alternative paths of technology development in the agriculture and energy sectors. In the energy sector, the central question is how to manage the transition away from the current reliance on conventional oil and gas. In the agricultural sector, the key issue concerns land productivity. Alternative technology bifurcations lead to a number of scenarios embedded and consistent within the overall theme of "prosperity via high technologies". All scenarios provide the high quantities of clean and convenient energy forms and diverse, high quality food demanded in an affluent world. Because technological change is cumulative, it can go in alternative, mutually exclusive directions, i.e., changes become "path dependent". Alternative directions unfold around the interrelated cluster of variables of resource availability and conversion technologies in both energy and agriculture. For instance, new technologies may enable humanity to tap either the vast quantities of fossil resources existing in the form of coal, unconventional oil, and gas with technologies that are both highly economic, efficient, and clean in terms of traditional pollutants, such as particulates or sulphur. Alternatively, technological change could unfold favouring non-fossil technologies and resources, such as nuclear and renewables. A similar bifurcation unfolds in the agricultural sector. In one sub-scenario, only incremental improvements are achieved in farming practices and land productivity. This is combined with a gradual global diffusion of meat-based diets. Both of these trends are land- (and deforestation-) intensive. Alternatively, global agriculture could move in the direction of genetically engineered, high productivity crops and "sea-farming," combined with a quality- and health-oriented diet based on fish and vegetables, both of which are relatively less land intensive. As a result, GHG emissions range widely even for otherwise similar scenario characteristics.

3.21 Energy Resources/Technology

Resource availability and technology are tightly interrelated. The "Golden Economic Age" of high productivity growth results from substantial technological innovation. Both contribute to economic growth, expansion of accessible resources, and improved efficiency in resource use. Factor productivity improvements occur across the board for agricultural land, materials, and energy. Improvement rates largely follow long-term historical trends and are entirely technology- and income- driven. Energy intensity (total commercial and traditional primary energy use per unit of

GDP) improves at an aggregate global rate of 1.5 percent per year. Improvement rates vary across regions as a function of distance from the productivity frontier and the turnover rates of capital stock. *Ceteris paribus*, improvement rates are higher in regions with currently lower efficiency and greater than average GDP growth. This assumes no particular policy intervention or additional price regulation apart from the ones consistent with a free market environment (i.e. price subsidies are removed, and full costing principles are established).

Per capita final energy use gradually converges as income gaps close. Final energy use per capita in non-Annex-I countries would reach approximately 85 GJ (2 tons of oil equivalent) by 2050 and approximately 125 GJ (3 toe) by 2100, i.e., about the current average of OECD countries outside North America. Despite improvements in productivity and efficiency, the high income levels lead to resource use close to the upper bounds of the scenarios available in the literature. For instance, global final energy use would increase to approximately 1000 EJ by 2100.

The scenarios developed are a function of the different directions taken by technological change. The key question is which primary resources may become economically accessible in the future, and which technologies will become available to convert these primary resources into the final goods and services demanded by consumers. In the energy area, resources/technologies are key variables in determining the timing and nature of the transition away from currently dominant conventional oil and gas.

Four pathways are possible:

1. Progress across all resources and technologies.
2. "Clean coal" technologies: environmentally friendly except for GHG emissions and possible resource extraction impacts.
3. "Oil/Gas": smooth transition from conventional to unconventional oil and gas, tapping the vast occurrences of unconventional fossil fuels, including methane clathrates.
4. "Bio-Nuclear": rapid technological progress in non-fossil supply and end-use technologies, e.g. renewables, such as solar and biomass combustion, nuclear and hydrogen-fuelled end-use devices, such as fuel cells.

For the scenario quantification, a number of contrasting cases, characterised by the main energy form used in the second half of the 21st century, have been evaluated with the aid of formal energy models:

1. The dominance of Non-Fossil fuels -- the "Bio-Nuclear" scenario (A1R).
2. The dominance of unconventional gas, including hydrates, and oil (A1G)
3. The dominance of "Clean Coal" (A1C)

A brief scenario taxonomy is given below.

Scenario

Dominant

Oil/Gas Resource

Technology Improvements

	Fuel Availability	Coal	Oil/Gas	Non-fossil
AlR	Non-fossil Medium (<50 ZJ)	Low	Medium	High
AlG	Oil/Gas High (>75 ZJ)	Low	High	Low
AlC	Coal Low (<35 ZJ)	High	Low	Low

*

Depending on the assumed availability of oil and gas, (low/medium/high) and

corresponding improvements in production and conversion technologies for coal, oil/gas, and non-fossil technologies, different energy systems structures unfold. For instance, in the dynamic technology cases, liquid fuels from coal or unconventional oil/gas resources would become available

at less than \$30 /barrel, with costs falling further by about one percent

per year with exploitation of learning curve effects. Non-fossil electricity (photovoltaics, new nuclear) would become available at costs of

less than 10 mills/kWh (\$.01/kWh) and continue to improve further as a result of learning curve effects. The basic premise of the "dynamic technology" scenarios is that energy services could be delivered at long-run costs not higher than today, but with technologies having radically different characteristics, including environmental. In the event

that such technology dynamics do not materialise, energy costs and prices would be significantly higher than suggested above -- illustrative model runs suggest energy demand would be up to 20 percent lower for a fossil scenario without significant cost improvements .

3.22 Agriculture

In the agricultural sector, two contrasting scenarios of land productivity

could unfold, depending on the nature of advances in agricultural technologies. However, CO2 emissions from land use changes could range from 0.5 (low) to 1.5 (high) GtC by 2030 and from -1 to -2 (low) to zero (high) GtC emissions by 2100. In the latter case tropical forests essentially become depleted as a result of land-use conversions for agriculture and biomass fuel plantations. In the former case, land productivity gains are so substantial that ploughing of marginal agricultural land is no longer economically feasible and is abandoned, following recent trends in the OECD. The resulting expansion of forest cover leads to a net sequestration of atmospheric CO2.

3.23 Scenario Quantification

An initial scenario quantification in terms of population, GDP, energy use,

and CO2 emissions for the three energy resource/technology sub-scenarios is

summarised in Appendix 1 . The global scenario for 2100 is also summarised

in the form of a snowflake diagram. All scenario quantifications are

tentative and subject to revisions.
[Figure: "Snowflake" for A1 scenarios]

3.24 CO2 Emissions

The diverging pathways of resource availability and technological change characteristic of the three scenarios examined result in a wide range of annual CO2 emissions: from 10 to 33 GtC by 2100. It is interesting to note that the emissions of the two "fossil fuel" sub-scenarios, "clean coal" and "oil and gas," are quite close to each other (33 GtC versus 29 GtC). Continued reliance on oil and gas, coupled with demand growth, explain the emission patterns for the oil/gas scenario. Coal is the only fossil resource available in the "clean coal" scenario. Therefore, over time coal is increasingly required for conversion into premium fuels such as synliquids and syngas. This conversion "deepening" leads to a feedstock premium for coal and increases the market potential of non-fossil fuels. CO2 emissions are therefore not as high as in traditional coal-intensive scenarios.

4. Sustainable Development (B1)

The central elements of this scenario family include high levels of environmental and social consciousness, successful governance including major social innovation, and reductions in income and social inequality. Successful forms of governance allow many problems which are currently hard or difficult to resolve to fall within the competency of government and other organisations. Solutions reflect a wide stakeholder dialogue leading to consent on international environmental and social agreements. This is coupled with bottom-up solutions to problems, which reflect wide success in getting broad-based support within communities. The concerns over global sustainable development, expressed in a myriad of environmental and social issues, results in the eventual successful management of the interaction between human activities and the biosphere. While no explicit climate policy is undertaken, other kinds of initiatives lead to lower energy use, and clean energy systems, which significantly reduce greenhouse gas emissions. Besides cleaning up air quality, there is emphasis on improving the availability and quality of water.

4.1 Key Scenario Drivers and their Relationships

4.11 Technological Development

High levels of technological development focused on achieving sustainable development leads to high levels of material and energy saving, innovations in emissions control technology, as well as labour productivity. The latter is essential to support the rapid growth in personal income, given

that a major increase in labour force participation is implicit in the equity assumptions. Technologies tend to be implemented in an industrial ecology mode, implying a much more highly integrated form of industrial production than at present. Information technology achieves a global spread, and is fully integrated into production technologies. Advances in international institutions permit the rapid diffusion of new technologies -- R&D approaches two percent of GDP.

4.12 Population and Economic Development

Population -- reaches only 9 billion by 2100 -- due to a faster than expected completion of the demographic transition arising from a large increase of women in the labour force, universal literacy, and concern for the environmental impacts of high population levels. The potential impacts of ageing populations which emerge from this low level of population growth are offset by relatively high levels of immigration, which reduce the negative impacts of ageing populations on savings and the ability of societies to adapt and implement new and cleaner technologies. This world has a faster than expected transition from traditional to modern economic sectors throughout the developing world. In addition, widespread education leads to high labour productivity, and high labour force participation. Migration serves to sustain the size of the labour force in developed countries, which helps to maintain their growth in per capita income. Developing countries experience few institutional failures, enabling them to grow at or near the historical upper bounds of experience given their per capita incomes. This yields a world of high levels of economic activity, with significant and deliberate progress being made with respect to international and national inequality of income. The current order of magnitude differences in income between developing and developed countries are reduced to a factor of two, with moderate growth continuing to occur in OECD countries. Gross World Product (GWP) reaches \$350 trillion by 2100 and average global incomes \$40,000 per capita. Economic development is balanced and, given the high environmental consciousness and institutional effectiveness, this leads to a better quality environment, with many of the aspects of rapid growth being anticipated and dealt with effectively. Active management of income distribution is undertaken through use of taxes and subsidies. The composition of final demand will evolve to a mix reflecting lower use of materials and energy, thus easing the impact of high income levels.

4.13 Equity

In this world there is a preparedness to address issues of social and political equity. The increases in equity, reflect a shift in values which, with widespread education, leads to greater opportunity for all. New social inventions, such as the Grameen Bank's micro-credit schemes, are a significant contributor to an increase in institutional effectiveness and equity improvement.

4.14 Communications, Settlement Patterns and Environment

The social innovations and effective governance rest on high levels of communication, both in a passive (i.e. TV) and active sense. Governance systems reflect high levels of consent from those affected by decisions, and this consent arises out of active participation in the governance process.

Settlement patterns arise from design, and tend to reflect a distributed, compact, city design structure. This results in high amenity levels, and the careful design and location of these cities results in a lessening of the natural disasters which plague many cities today. Advanced hazard warning systems and careful design limit the impact of such disasters. Low emission technologies, and careful management of land use, preservation of large tracts of land, and active intervention to counteract the impacts of imprudent societal actions strengthen the resilience of the ecological system.

4.2 Scenarios

4.21 Energy Resources/Technology

Energy efficiency innovations, and successful institutional innovations disseminating their use, result in much lower levels of energy use relative

to historic patterns. The forward-looking nature of societal planning results in relatively smooth transitions to alternative energy systems as conventional oil and gas resources dwindle in availability. There is major

use of unconventional natural gas as fuel supply during the transition, but

the major push is towards renewable resources such as solar and wind.

The

impact of environmental concerns is a significant factor in the planning for new energy systems.

Two alternative energy systems, leading to two sub-scenarios, are considered to provide this energy:

1. Widespread expansion of natural gas, with a growing role for renewable energy (scenario B1N). Oil and coal are of lesser importance, especially post-2050. This transition is faster in the developed than in the developing countries.

2. A more rapid development of renewables, replacing coal and oil; the bulk

of the remaining energy coming from natural gas (scenario B1R).

4.22 Scenario Quantification

Per capita incomes in the developed world are close to ___ in 2100, while average per capita income in the developing world grows from ___ % of the developed world in 1990 to ___ % in 2100. Energy per unit of output continues to fall at about historical rates in the developed countries, resulting in total energy use of ___ EJ in 2100. Rapid spread of technology from developed to developing countries enables an energy growth

of ___ percent less than GDP, resulting in total energy use of ___ EJ in the developing part of the world

An initial quantification of the scenarios in terms of population, GDP, energy use, and CO2 emissions for the two energy resource/technology scenarios is summarised in Appendix 1. The global scenario for 2100 is also summarised in the form of a snowflake diagram. All scenario quantifications are tentative and subject to revisions.

[Figure: "Snowflake" for B1 scenarios]

4.23 CO2 Emissions

The range of carbon in CO2 emissions for the scenarios is 7.5 to 20 billion tons in 2100, reflecting 3 and 2 percent per year reductions in carbon per unit of GDP

5. Divided World (A2)

In a retreat from the globalising trends of the previous century, the world

"consolidates" into a series of roughly continental economic regions. Regions pursue different economic strategies based on the resources and options available to them. Trade within economic regions increases, while

trade between regions is controlled by tariff and non-tariff barriers to support the region's economic strategy. High income regions restrict immigration and impose selective controls on technology transfer to maintain high incomes for their residents.

High income regions encourage higher levels of education to increase the productivity of their labour force. They impose restrictions on immigrants,

except skilled immigrants, to keep per capita incomes high. They also try

to impose selective restrictions on technology transfer to maintain the productivity of their labour force.

Low income regions are only able to increase per capita incomes slowly. They do not have the resources to invest in educating the labour force or in research and development. Investment from other regions is constrained.

Thus exports are primarily products manufactured with low cost labour and

some natural resource-intensive products. Population growth is high relative to high income regions. Income inequality becomes more pronounced

within low income regions and increases between regions.

Regions use non-tariff barriers, such as differences in standards and

labelling requirements, to limit trade. Trade is also dampened by differences in tastes in products. These factors favour the use of resources found within each region. Regions that have abundant coal resources but very limited oil resources, for example, encourage use of "local" coal by heavy industries and electric utilities while allowing restricting free imports of crude oil and petroleum products .

5.1 Key Scenario Drivers and their Relationships

5.11 Population and Economic Development

Fertility rates vary among regions. North America, Northwest Europe and Asia experience falling fertility rates and populations. The Middle East, Africa, and to some extent, Southern Europe and South America see rising population although the rate of growth decreases. This leads to a shift in the world population balance from the Indian sub-continent and South East Asia to the Middle East and Africa by the end of the century. World population reaches 16 billion by 2100. Regional economies emphasise self-sufficiency with wide variations in growth levels. Average global economic growth is relatively low at around 2.5%/year, leading to a GWP of \$250 trillion by 2100. Trade across regions consists primarily of raw materials and semi-finished goods in a relatively low trust world where dependence on other regions is minimised.

5.12 Government and Geopolitics

National boundaries become less important within the regions as an increasing share of policy is agreed at the regional level. This allows considerable cultural diversity within regions. Governmental style is also diverse across regions. In some, government and religion strengthen their links, in others, secular democracy is maintained or consolidated. Education is strengthened in most regions with a deepening understanding of cultural history and religion. The growing strength of the economic regions, and their competing economic interests, lead to reduced international co-operation. Global environmental, economic and social issues are subject to relatively weak governance. Conflicts between ethnic and religious groups within economic regions become less violent as a result of economic pressures on the parties. Where ethnic and religious violence persists, the groups are excluded from the economic region. Thus wars occur in the boundary zones between economic regions. Wars may also occur near regional boundaries for control of scarce natural resources.

5.13 Technology Developments

While underlying science is conducted in all regions an information about scientific developments are available world-wide, consumption and

production patterns and hence, technology and practices, are determined by local circumstances.

Research activity increases in all regions; in high income regions due to the need to increase productivity with limited regional resources and in low income regions due to the growing size of the population.

Restrictions

on transfer of some technologies to other regions is widespread.

High income regions invest heavily in education to enhance labour productivity. Some high-income regions move towards broad-based education for a knowledge-based society. Others move towards practical education (lots of science and engineering) for an advanced industrial society.

Low

income regions are not able to invest as heavily in education, but the levels (and future rates of economic growth, vary significantly).

Technological change is rapid in some regions, slow in others, with industry adjusting to local resource endowments, cultural characteristics and education levels.

5.14 Communication and Settlement Patterns

Languages become more uniform within regions, but globally more diverse. Speakers of the main world languages are fairly evenly split.

Computerised

translation eliminates the language barrier to technology diffusion and economic development.

Urban concentration continues except in Europe and North America, which move towards larger numbers of smaller cities and towns. Urban shares of population in other countries rise to current OECD levels by 2020. While there is free movement within most regions, there is very little migration

among regions. Refugee problems are confined to edge areas, for example, Baltics and Tibet.

5.15 Environmental Concerns

Environmental management follow pragmatic paths: with rising incomes, people become increasingly concerned first about urban pollution, then about regional pollution, finally about global problems. In this world, global environmental problems are discussed extensively but the will to tackle them is lacking. Propensity to worry about the environment is regionally variable. Sulphur emissions are rapidly reduced in South and South East Asia due to the impacts on agriculture but increase in Africa with exploitation of coal and minerals there.

5.2 Scenarios

Divided World is explored through a single scenario.

5.21 Resource Availability

Regions try to use their resource endowment for their economic advantage. Regions with abundant energy and mineral resources use those resources domestically and to produce exports (surplus to expected long-term needs).

Regions poor in energy and mineral resources will minimise their dependence on these resources. High-income, resource-poor regions will develop as service-based, dematerialised economies, while low-income, resource-poor regions are forced to limit their consumption of resources.

High-income regions without indigenous oil and gas undergo a near-complete conversion to an energy economy based on nuclear or renewable based electricity and synthetic gases and liquids by 2050. India and China adopt these technologies at the largely exhausting domestic coal reserves by 2050. Renewable input, zero waste industry is pioneered in South East Asia and adopted in Europe, minimising mineral and fossil fuel requirements by 2050. Oil and gas-rich regions (North Africa, the Middle East, Central Asia, Russia) continue to use fossil fuels but towards 2050 the falling cost of renewable technology (wind and biomass in Russia, photovoltaic in the other regions) begins to make them competitive even in these regions

5.22 Scenario Quantification

An initial quantification of the scenario in terms of population, GDP, energy use, and CO2 emissions is summarised in Appendix 1. The global scenario for 2100 is also summarised in the form of a snowflake diagram. All scenario quantifications are tentative and subject to revisions. [Figure: "Snowflake" for A2 scenarios]

5.23 CO2 Emissions

The level of carbon in CO2 emissions for the scenario is 15 billion tons in 2100 as only oil and gas rich regions continue to use fossil fuels.

6. Regional Stewardship (B2)

"Regional Stewardship" is based on a natural evolution of the present institutional policies and structures. As such it does not incorporate major geopolitical power shifts or fundamental technological discontinuities. There is relatively low trust, global agreements are difficult to reach and the result is 'multiple islands' with inward looking policies.

This is a world of good intentions, which are not capable of being implemented. The late 20th century value shift towards environmental stewardship continues, for example as envisioned in the Cairo and Rio Programs of Action, with increasing recognition of the importance of human welfare and inequity. These concerns cannot be tackled at a global level and are resolved regionally or locally. Environmental solutions are tempered by the desire for balance with economic goals in many areas - but poor governance means that meeting the needs of the poor and future generations is hampered by limited prosperity. Families think seriously about the fact that their offspring may be dealing

with a more ecologically stressed world, moreover one with limited financial resources for dealing with such problems. Education levels are high so that the ability of families to internalise global concerns in their family planning decisions is also high. The relative stabilisation of world population growth after 2050 leads to general optimism about the ability of society to solve problems such as food and water supply.

6.1 Key Scenario Drivers and their Relationships

6.11 Population

Both local governance and environmental concerns limit population growth. The world largely supports efforts to reduce unwanted births both as a social service but also because there is an implicit belief that even increasing populations have severe environmental consequences. Education and welfare programs for the young and illiterate are widely pursued.

Population stabilises at 10.5 billion people by 2100. Since economic growth is relatively slow, fertility rates do not decline strongly. But, the effect of fertility rate declines on lowering population size outweigh those of mortality rate decreases increasing population size.

The stabilisation of global population (largely after 2050) leads to a new atmosphere for social planning. It becomes considerably easier than at present for education, health care and pension programs. Age cohort sizes are much more stable through time than at present, although of course, overall ageing continues.

6.12 Economic Development

GWP grows to around 240 trillion \$ in 2100 with a North/South income ratio of approximately 7/1 (presently 13/1). Concerns about the ecological costs of consumerist lifestyles receive wide attention and attempts are made, first in industrial countries, but later in developing countries, to seek satisfaction through community activities rather than high consumption. Overall people are eager to find alternatives to the high income world of materialism.

6.13 Governance

Governance is weak globally but strong nationally and regionally. Deliberate policies to limit trade for environmental and social reasons hinder the transfer of technologies. However pollution trading concepts catch on as a way of driving down the costs of pollution control. International alliances occur based on particular national circumstances, such as in the development of biomass technologies. This fragmentation gives rise to pockets of environmental and social justice activists. Environmental policies vary widely across regions, for example in acceptable sulphur emission levels. NGO and public interest groups are strong, influential and busy.

6.14 Equity

While strong redistribution policies are enacted within regions to reduce income disparity, income differences between regions persist globally throughout the century and even increases in absolute terms, although the relative inequity decreases. The mechanism by which global equity increases relates in part to population dynamics: as fertility rates decline in developing countries, the decrease in youth dependency ratios leads to an increase in savings rate and strengthened economic growth during the first half of the century. In the developed regions, by contrast, ageing becomes an increasing drag on economic growth in helping to converge global incomes, concerns about the persistence of income inequality world-wide are swamped by the local concerns and conscious policies to limit international trade.

6.15 Settlement Patterns

A strong deurbanization trend occurs in this world because of increasing concern about the marginalization of the very poor that accompanies massive urbanisation. There are also concerns about managing large transient populations that migrate seasonally to cities for short term employment, for example in the construction industry.

Immigration is controlled but accepted, partly to compensate for very low fertility rates in some regions and partly to help economic development worldwide without the problems of uncontrolled globalisation.

6.16 Environmental Policy

Environmental improvement is strongly pursued although regional policies vary widely such as with sulphur controls. Marked reductions in S, CH₄, deforestation, CFCs and N₂O occur and water quality is addressed. Ecological resilience is not seen as high. The environment is viewed as quite fragile and requiring careful policy stewardship. Resource extraction is viewed as intrinsically problematic and scepticism persists regarding the ability of society to prevent environmental disasters like the Valdez oil spill and Kuwaiti oil fires. Indeed the world is increasingly sensitive about and intolerant of such events and much tension exists concerning this aspect of development. Environment groups lobby hard on these themes and paint a picture of rapidly depleting natural resources.

6.2 Scenarios

6.21 Energy Resources/Technology

Because of the concern about ecological fragility, alternative and renewable energy systems are viewed with much hope and are socially and politically encouraged. Biomass technologies and policies are invigorated.

The labour and land intensive developing countries pursue biomass production while the capital intensive developed regions develop the required technologies. A degree of co-operation coalesces about such mutually symbiotic activities.

Consumers accept a rather long return in evaluating energy-efficiency investments. Mass transit systems are very successful and profitable. Advances in transportation technology are rapid.

Hydroelectric power is a constrained bag. Dams are viewed with disdain because there are soon no more wild rivers anywhere and the rights of indigenous people have been egregiously violated. Although they are relatively clean from the perspective of carbon emissions, their effects on indigenous people (mercury poisoning of fish, etc.) becomes unacceptable. Decommissioning dams is widespread to restore pristine ecological systems downstream.

Reduction in carbon intensity is not viewed as a policy goal but it declines for other reasons. It is a frugal world with limited resource availability and so the paradigm grows that it is less costly to save energy than it is to buy it and use it. This spurs the development of technologies that use carbon more efficiently. In addition the accompanying emissions of NOx and SOx and tropospheric ozone are increasingly viewed as unacceptable.

6.23 Scenario Quantification

An initial scenario quantification in terms of population, GDP, energy use, and CO2 emissions for the scenario is summarised in Appendix 1. Energy intensity declines at a rate of 1.3%/year to a value of 0.12 toe/\$1000 in 2100. This represents a total global energy usage in 2100 of 1250 EJ, of which 300 EJ is oil and gas; 100 EJ coal and 900 EJ is non-carbon renewables, with nuclear's role limited.

The global scenario for 2100 is also summarised in the form of a snowflake diagram. All scenario quantifications are tentative and subject to revisions.

[Figure: "Snowflake" for B2 scenario]

6.24 CO2 Emissions

By 2100 CO2 emissions 11.5 GtC/year, of which 5 GtC/year is emitted by the North and 6.5 GtC/year by the South. Carbon intensity declines at a rate of 0.8%/year to 2100, to a value of 0.3 tC/toe, some 50% of today's value.

7. Scenario Comparisons

Dear Keith

Yesterday we had the final meeting to a national research program climate and natural catastrophies. Local authorities and Grassel, WMO summarised the major open questions on which Switzerland could work:

- Changes of Forest and treeline borders eg. subalpine, or invasion of evergreen species in the chestnut forests in the Tessin
- long term chronologies (they spoke about climate)
- seasonal chronologies
- frequency and intensity of extreme climatic events.
- amount of anthropogenic input on climate and natural catastrophies.
- reconstruction of precipitations
- influence of natural phenomena as volcanoes and el nino on climate

Nowbody said anything about growth but few were aware of the local validity of the studies made in Switzerland.

Our actual studies fit perfectly to this topics. For the future (discussion in Kopenhagen) I see the following condensation points:

-continue millennial temperature sensitive chronologies. Some money should go to Taimyr and Yamal and perhaps French Alps.

-start with a precipitation sensitive network in Eurasia. Pinus, Juniperus in a transect from Spain to Tibet including dry sites in Sibiria. Partner could be Inst. of Geography, Bonn (Jan Esper) and Birmensdorf.

-Analysis of recovery of upper timberlines in Putorana mountains in north-central Sibiria, (similar study like Shiyatov in Polar Ural). A Vice director of the Inst. of Forest in Krasnoyarsk made a little Proposal (Dr. Abramov). I have a PhD Student who make the same in the Swiss Alps near St. Moritz.

-Growth-climate studies in a test region in central Sibiria. Very good is the baikal region. There is a very steep precipitation gradient, 200mm - 1800mm in a distance of 40 km. and in accordance a steep vegetation gradient from the steppe to pine forest to Abies sibirica stands. Victor Voronin made

a little proposal) At least one valley in the Abies region in the south of lake Baikal is heavily polluted An almost identical study has been made in southern Germany(Spiecker) in a transect from Lorraine to the black forest mill,(SO2).

-Reconstruction of extreme events in Central Europe (R. Vogels thesis shows how to do it) I am convinced that we could gather much mor material across Europe. That could be a topic for a thesis. It must not be part of an EU-proposal.

Can we discuss this suggestions at Kopenhagen?

Sincerely Fritz

Subject: meeting next week
Date: Tue, 21 Apr 1998 15:53:20 +0200
Cc: kuszko@uea.ac.uk

Dear Colleagues,

Due to the large number of participants at the Lead Authors meeting, the location has been changed from IPCC WG II TSU offices to the World Bank, H Building, 600 19th Street, N.W.

The closest metro stop to this building is Farragut West on the orange and blue lines. Take the 18th Street exit from the metro and go one block to 19th Street and then two blocks over to G Street. You will need a badge to get into the meeting, but someone will be there to help you with this. In any case, it may be a good idea to come a bit early on the first day to get checked in. The meeting begins at 8:30 a.m. Wednesday morning.

The Modelers meeting will still be held at the WG II TSU office as originally planned. That meeting starts at 8:30 a.m. on Monday morning. The address, once again, is 400 Virginia Avenue S.W., Suite 750,

Washington, D.C.

We look forward to seeing everyone in Washington.

Best regards,

Anne Johnson

Subject: RE: IPCC SRES Scenario Guidelines for Authors
Date: 08 May 1998 10:50:50 +0100

Find below guidelines on how to present the IS99 storylines and scenarios. Could you the nominated authors send me your first drafts as soon as possible.

In writing up your contribution could you cover the following areas, ideally structured as follows:

1. Scenario family narrative to discuss main themes, dynamics and a diagram showing 'grand logic'

2. Key Scenario Family Drivers and their Relationships

Topics you should cover include the following:

- * population
- * technology developments
- * governance and geopolitics
- * economic development
- * equity
- * communication and settlement patterns
- * environmental concerns/ecological resilience

3. Scenarios, include reasons for branches: this section should state clearly the reasons behind selection of scenarios and review the key highlights of the scenario quantification

- * energy resources/technology, include resource availability
- * land use and agriculture
- * scenario quantification, include snowflake
- * CO2 emissions

There may be other factors you wish to add to the paper.

Subject: Re: Something far more interesting
Date: Wed, 17 Jun 1998 12:03:13 -0400 (EDT)
Cc: t.osborn@uea.ac.uk

Dear Phil,

Of course I'll be happy to be on board. I think the opportunity for some direct collaboration between us (me, and you/tim/keith) is ripe, and the plan to compare and contrast different approaches and data and synthesize the different results is a good one. Though sidetracked by other projects recently, I remain committed to doing this with you guys, and to explore applications to synthetic datasets with manufactured biases/etc remains high priority. It sounds like it would all fit into the proposal you mention. There may be some overlap w/proposals we will eventually submit to NSF (renewal of our present funding), etc. by I don't see a problem with that in the least.

Once the collaboration is officially in place, I think that sharing of codes, data, etc. should not be a problem. I would be happy to make mine available, though can't promise its the most user friendly thing in the world.

In short, I like the idea. INclude me in, and let me know what you need from me (cv, etc.).

cheers,

mike

Subject: Scenarios issues
Date: Mon, 20 Jul 1998 18:00 +0000 (GMT)

Dear colleagues,

I will like to post here some correspondence which is clearly relevant for this "scenarios discussion group" regarding some issues related to the use of the new emission scenarios, simple models, etc. Please post any comments on these issues or any other issue that you may want to raise to the following address "scenarios@meto.gov.uk".

I have added the following experts to the list posted in my first Email:

P Wagner
R Watson
J Edmonds
S Smith
G Marland

Many thanks.

Maria Noguer

Issues raised by J Mitchell:

1. There are several uses for scenarios:
 - a) Conversion to concentration using chemistry models to produce forcing curves
 - b) Forcings for GCM runs
 - c) Use in simpler models to produce global mean curves of concentrations, forcing, temperature and sea level. This would requires a simple model which is documented and calibrated against one (preferably several) climate models. The final IPCC approved scenarios will not be available until February 2000, so we should decide now on which draft scenarios to use
2. The provisional emissions will be made available imminently. These need to be evaluated as there are four basic families and many variants. How is the median scenario defined?
3. What criteria are to be set for the simpler models used for global mean projections?

Issue raised by Tom Wigley and reponses:

Date: Mon, 13 Jul 1998 11:00:54 -0600 (MDT)

Subject: IPCC CO2 Emissions Scenarios

Dear Bob, Hugh, Naki and John,

Mike Hulme has told me something that is quite alarming about the soon-to-be-released 'IPCC' CO2 emissions scenarios. If this is correct, you/IPCC should try to remedy it as a matter of some urgency. He said that the new 'IPCC' CO2 emissions scenarios will still begin in 1990 and will not use observed (Marland) emissions for the 1990s.

You may either not realize, or not remember, that during the preparation of the SAR and (especially) TPs 2 and 4, IPCC was frequently criticized for using out-of-date emissions data that were manifestly wrong during the 1990s. It would be extremely embarrassing to be subject to the same criticism with the TAR. Indeed, since the criticism is a justifiable one, it would be inexcusable not to have responded to it.

Equally embarrassing should be the fact that, in the published literature (my 1997 Nature and 1998 GRL papers), this 'error' has already been avoided.

How can you get around this problem? Ideally, the energy-economics models need to be revised to begin in or around 2000 instead of 1990. Indeed, in talking to Rich Richels about this issue, as well as echoing my concern, he noted that his model (MERGE) is currently being updated in just this way. He also pointed out that beginning an energy-economics model run in 1990 leads to considerable 'flexibility' in 2000 emissions; when, in fact,

the 2000 emissions will already be fixed and known by the time the TAR comes out.

It is probably impossible to make this ideal type of 'fix', but a 'fix' can still be made. What you could do is just what I have done in the above two papers. This is a simple procedure that CAN be used since it is in the published literature. All I did was use observed emissions to 1996 (as far as data were available), linearly extrapolate these to 2000 (under the assumption that this was a better projection than the corresponding IS92a projection), and then use IS92a CHANGES from 2000. You may be able to improve on the second step, but this is unimportant. The crucial thing is to get the beginning years of the record to match observed emissions as far as such data are available.

The above, by the way, does not have to be applied to emissions from land-use change because of the way we deal with initialization with the carbon cycle models. We do not use historical land-use- change emissions.

You may argue that, in terms of projected CO2 concentrations, incorrect 1990s emissions have only a minor effect. This is such an obviously specious argument that I won't bother to discuss it. Not least, it will not satisfy the critics.

A parallel issue does, however, arise with the CO2 concentration stabilization profiles. The 'S' profiles are already ludicrous, since their concentrations and implied emissions already diverge markedly from observations. The WRE profiles diverge less, but still enough for me to deem that they need revising. I have, in fact, already done this. I would be happy to pass the new profiles on to IPCC.

Best wishes,
Tom

=====
>From Robert Watson on July 13:

Tom: I appreciate you bringing this critical issue to the fore - you are absolutely right that we must not look naive. I assume that Naki and Jon et al. Will deal with this while I am on vacation for the next four days.

Bob

To: Tom Wigley <wigley@meeke.UCAR.EDU>
Subject: Re: IPCC CO2 Emissions Scenarios

Tom,

I raised this issue at the scoping meeting in Bad (very bad) Munstereieffel, where it was greeted with general agreement but it appeared to come as a complete surprise to many that scenarios should have a relationship to reality.

There was also general mild surprise at the degree of non GCM-community interest in following Kyoto and stabilization rather than 1% per year and similar reactions to the fact that 1% year doubles the current rate of change.

But the wind is shifting

Subject: Re: IPCC CO2 Emissions Scenarios

Dear Tom,

I got the same impression from Hugh's talk during the last week Community Meeting on IA, which was sponsored by NSF. It does not matter so much whether the starting point for the scenario calculations is 1990 or 2000. The main concern is that the emission scenarios should reflect the recent changes in fossil emissions, which show a decreasing trend from 1990 to 1995 in Annex B emissions. Using projected emissions that are incorrect, rather than updating them with observed emissions, is clearly not acceptable.

I agree with you that the effects of these emissions on CO2 concentration is minor. However, recent observed emissions will have a major impact on estimates of the cost of CO2 abatement, which depend mainly on cumulative emissions rather than on concentration. It is important, especially in light of Kyoto commitments, not to produce inaccurate emission pathways that overestimate emissions from 1990-2000, since they may be used as baselines for producing cost estimates.

Cheers! Atul

Subject: RE: IPCC CO2 Emissions Scenarios

Dear Tom et al

In setting up the MiniCAM to do the scenario work for the SRES, we tuned the 2005 energy and hence emissions numbers to reproduce the latest IEA forecast, which explicitly incorporates the slowdown in 1990 to 1995. The only problem here is that informal feedback from within Russia(Igor Bashmakov) suggests the IEA data significantly overstate the reduction in energy use. Our scenarios all go through the short term forecast for 2005 and then diverge onto alternative paths.

Getting a good handle on recent historical data and a consistent/reasonable forecast for tuning the short term aspect of the scenarios is going to be increasingly critical as we try to sort out strategies and costs of strategies. This is a separate problem from the long term scenario work, and requires rather different tools.

cheers, hugh

Dave Schimel <schimel@ucar.edu>, Gregg Marland <gum@ornl.gov>,
ssmith@ucar.edu
Subject: RE: IPCC CO2 Emissions Scenarios

Dear all,

I appreciate the responses regarding my concern about the new 'IPCC' fossil CO2 emissions scenarios. However, no-one seems to be willing to grasp the nettle and suggest what can be done about it. From what Hugh says, all scenarios go through the same 2005 value, so this suggests an obvious 'fix'.

(I am curious to know what this 2005 value is, and how close it is to what I used in my Kyoto papers.)

Hugh also suggests the 'IPCC' 2005 value may be open to improvement, but I presume it is too late to do this now. So ... what should be done? The obvious solution would be to use Gregg Marland's 'observed' values as far as they go, and then linearly interpolate from his latest year to 2005.

When I did my work, I had Gregg's values to 1995, and was able to make a good guess from what he told me about what the 1996 value would be. By now, 1996 should be available, and a good estimate may be possible for 1997. If so, then the linear interpolation would go over 1997 to 2005.

Do you all agree with this strategy? ... or does someone have a better idea??

I'm copying this to Gregg to see what more recent data he can provide.

Cheers,

Tom

Subject: Next SRES Meeting in Beijing, 7-9 October
Date: Tue, 25 Aug 1998 17:31:41 +0200
Cc: johnson@uea.ac.uk, kuszko@uea.ac.uk, dowds@uea.ac.uk

Dear Colleagues,

Zhou Dadi has been kind enough to organize the next SRES Lead Authors meeting in Beijing, China, to be held on 7-9 October, 1998. Dadi will provide us with more detailed information on meeting logistics in the near future, and I will send out a meeting agenda as we get closer to the meeting date. Basically, there are four items that need to be discussed at the meeting: 1) SRES progress to date; 2) the open process; 3) scenario revisions and additional work; and 4) planning the final report.

Please mark you calendars for this date and RSVP to both Zhou Dadi (becon@public3.bta.net.cn) and Anne Johnson (johnson@iiasa.ac.at) as soon as possible I will be out of the office 10-26 September and will not be able to receive messages during this time.

I look forward to seeing you in Beijing.

Naki

Dear Colleagues,

This is a follow up on the earlier announcement of the next SRES Meeting. First, I would like to thank all those of you who have confirmed that you will join us in Beijing. Unfortunately, some of our colleagues also had to cancel due to other commitments. Attached you will find the venue of the meeting and hotel that Dadi reserved for us at a special discounted price. My proposal is to convene at 13:00 hours on 7 October and try to finish on early afternoon on 9 October so that you have some free time left for sight-seeing before we all depart.

I will soon send to all of you formal invitation letters on IIASA letter-head just in the case you need it for travel approval (unless you cancel your participation in the meantime). Dadi will send you a similar invitation letter to use in order to obtain a visa for China.

Appended is my last e-mail concerning this meeting in case you did not receive a copy. In the attachment to this e-mail you will find two letters. One is from IPCC outlining the possible role of scenarios in IPCC assessment (Microsoft Photo Editor file). It is important for our work as it indicates possible uses of new IPCC emissions scenarios. One of the agenda items at the meeting will indeed be to discuss which of our marker scenarios we recommend be used in the interim period before our scenarios are approved by IPCC in early 2000. The other letter is also from IPCC announcing the SRES web-site (PowerPoint file). The web-site includes most of the scenario variants we have developed to date. Please circulate this second letter as widely as you can because we need as much feedback from the wider community of possible users as we can obtain.

Please let us know as soon as possible whether you are planing to attend.

I hope to see you all in China.

Regards, Naki

Venue:

National Meteorological Administration (No. 46 Baishiqiao Road, Haidian District, Beijing).

Accommodation:

Olympic Hotel (No. 48 Baishiqiao Road, Haidian District, Beijing, Tel: 086-10-62176688); discounted Price: US\$65+15% service costs.

Meeting Announcement:

Dear Colleagues,

Dear Keith,

Some days ago I came back from the Polar Ural Mountains. I was there about 30 days making photos from the points where I have made photos 35-40 years ago and evaluating the changes which were happened during this period. Unfortunately, Rashit could not be able to go to the Yamal Peninsula for collecting subfossil wood this summer as a result of deficiency of money.

I am glad that we have been successful in INTAS proposal. Financial situation in our country so terrible that we will not work successfully without support from international grants.

Yesterday I have sent by post the signed form (official power of attorney). If you have any additional information concerning this grant, please give me know.

I wish the best to you, your family and Phil.

Sincerely yours
Stepan Shiyatov

Subject: RE: WGI emissions/scenarios conference
Date: Wed, 16 Sep 1998 09:15 +0000 (GMT)

Mike

I think the problem is the same one as in 1988 and 1994. In order to answer the question: "what is IPCC's best estimate of climate change over the next hundred years, and the uncertainties?" we need a single best estimate of emissions (plus a range of uncertainty). In the same way as modellers say "here is our best estimate of climate sensitivity plus a range" then the SRES group should do the same thing. Of course they can make all the usual disclaimers and talk about surprises just as the climate modellers do. But NOT to come up with an estimate for a Business as Usual emissions scenario (plus a range, of 6GtC to 30GtC at 2100) seems to be ducking responsibilities. "Getting away from single number answers" is very laudable scientifically, but it presents policymakers (for whom the whole IPCC exercise is undertaken) with a problem. As long as there is a central estimate and a range, the surely both communities could be happy, as they ultimately were with BaU in 1990 and IS92a in 1995?

Geoff

Subject: WGI emissions/scenarios conference

Dear All,

Here are three comments on the questions raised by WGI TSU on 7 Sept. and by some of the other contributions to the discussion about scenarios for IPCC TAR. I am commenting from the perspective of a climate scenario constructor servicing the impacts research community:

1. The SRES Working Group have identified 4 Marker Scenarios (out of a much larger range, although these 4 largely capture the range). I think the choice is good. I do not see why some modelling centres should not be able to run all 4 emissions scenarios through their GCM. From an impacts perspective I believe this would be very desirable and would enable a fair

range of climate change scenarios to be used in impacts work using direct GCM output (without the need for scaling). And if all four Markers could be run through more than one GCM (i.e., with different climate sensitivities) then impacts work would have an even better sample of the possible climate change space to analyse. These aspects of uncertainty seem to me to be critical for impacts people (and integrated assessors) to explore, to get us away from single number 'answers'.

2. If a single emissions scenario *has* to be adopted by some GCM groups, B2 seems to have the recommendation from Naki (and maybe SRES too - the storyline refers to it as 'dynamics as usual'). I think there are probably good reasons why SO₂ emissions fall so much in this storyline - regional rather than global solutions and the encouragement of environmental protection. The fact that the reduced C emissions relative to IS92a are offset by the big fall in SO₂ emissions (the net global warming in B2 is actually slightly higher than IS92a if aerosol effects are included) should simply be seen as a reflection of a more carefully worked out storyline than was the case with IS92a. I do not think it a good idea (indeed, I think it would be a very *bad* idea) for GCM centres to mix-and-match elements of IS92 and SRES98 scenarios - the TAR should try and stick with the SRES stories and emissions wherever possible. The internal consistency in these storylines (and hopefully emissions) is important to maintain (especially later on for impacts work), and the thinking behind the SRES scenarios is considerably better than was achieved in the IS92 scenarios.

3. The problem of different Markers having different 1990 emissions values (and the fact that 1990s C emissions diverge from those observed) is more serious. By 2000 the four Markers range in C emissions from energy sources from 6.6GtC (B1) to 8.0 GtC (A1). Given where we are right now (about 6.7GtC in 1997) it seems daft to have such a range for only 2 years hence (as Tom Wigley has pointed out). For example, by the time TAR is published we will know that A1 C emissions for 2000 are too high by, say, 15%. Surely we need to impose a 'fix' on all 4 Markers to account for this. Such amendment may occur as a result of the SRES 'open-process', but this will take up to 12 months to be agreed and published. Should not someone (WGI or WGIII TSUs) impose a temporary solution now for climate modellers?

Similarly, something needs to be done for CH₄ and N₂O 1990 emissions. CH₄ 1990 emissions range from 281 to 481Tg in the 4 Markers (compared with 506Tg in IS92). Surely this range is not defensible. I think at the least we need some assurance from SRES that there has been some investigation into these differences and that they will withstand scientific scrutiny in peer review. Again, maybe the open-process may lead to revisions, but what

do climate modellers do in the meantime? [By the way, the difference in global warming by 2100 that the SRES CH4 and N2O scenarios generates relative to those in IS92a is between 0.05 and 0.3degC - lower in all cases].

Dear Phil,

Thanks for your message. I've chosen to "expand" the distribution list to include a few other individuals who can better address some of the key points you raise.

A meeting in January built around the AMS meeting (which should bring people into the Boulder vicinity) sounds like a good tentative plan. Peck? I'm assuming everyone on this list is a potential attendee...

As for your general comments, they get to some essential points. The modeling community leaders are probably about as skeptical about our paleo-reconstructions as we are of their sulphate aerosol parameterizations, flux corrections (or more worrying, supposed lack thereof in some cases!), and handling of the oh-so-important tropical Pacific ocean-atmosphere interface... So my personal philosophy is that more than one side here can benefit from extending the olive branch, and there are a few individuals in the modeling community who could benefit from slowing down on the stone throwing from their fragile glass tower :)

More to the point, though, I strongly believe the paleo community needs to present an honest but unified front regarding what we all agree we can definitely, probably, and simply not yet say about the climate of the past several centuries, and plan strategies that will allow us all to work towards improved reconstructions without stepping on each others toes. There's a challenge there, but one I'm sure we can all rise to. I am grateful to Peck for realizing that the time is ripe for a workshop in which we all strategize as a group towards these ends. I believe we all go into this in "good faith", and I'm very excited about what the workshop might produce, in particular, in terms of effective long-term strategies.

I share Phil's concern about getting things "straightened out" before the IPCC report. As one of the lead authors on the "observed climate variation and change" chapter for the 3rd assessment

report, a key goal of mine will be to present fairly and accurately all of our different efforts, and the common denominator amongst them...

I also understand all-to-well Phil's concerns about free data exchange. In fact, we've been working closely w/ Peck to get every aspect of our reconstructions, including calibration/verification statistics, etc., available on-line at NGDC. The one catch w/ the paleo network is that a few of the indicators we used were provided us under conditions that they not yet be passed along (this includes, I believe, the Moroccan tree rings, and some others. And at least one important indicator--Malcolm's Yakutia record--was as yet unpublished. Not myself knowing the details of the proprietary issues involved here, I have resisted simply putting our entire multiproxy network out their for public consumption. But working w/ Peck and Malcolm, I'm sure we can do this appropriately and quickly. That's an example of a key issue that would be on the table at the workshop in question.

-----PHIL'S MESSAGE TO PECK-----

Peck,

Thanks for the comments on the paper in The Holocene ! The paper stems from work Keith and I have been doing with the Climate Change Detection group headed by Tim Barnett. It is much toned down from some of the things about paleo data that Tim and Simon Tett wanted to say. Long paleo series (either the individual ones or regional/hemispheric averages) have got to be good before these sorts of people will begin to use them and believe they tell us something about variability in the past - something that cannot be got from long control runs of GCMs.

A small meeting would be a good idea, therefore. Mike Mann knows the next few times I'll be in the US. The first possible date for him is the AMS annual meeting in Dallas in Jan 99 - maybe we can tag something onto the end of this for a day or two. I'll let you and Mike work something out on this. I'm also in the US for a meeting on Climate Extremes which is tentatively scheduled for March 9-13 in Asheville.

Prsentation of the paleo data is the key in all this. Tim Barnett was somewhat horrified by the coherency diagrams he produced (fig 9). He then produced Fig 10 from the GCM and that was not much better. Hidden between the lines of the paper is the theme that a number of us have been saying for years (especially Ray and Malcolm) that the LIA and MWE were not that global and not that different from today's

temperatures. Mike's paper in Nature reiterates this. Keith and I have been thinking of writing a forum piece for The Holocene addressing in somewhat provocative terms what paleoclimatologists should be doing with regard the detection issue and to some extent with respect to science in general - should be continue using terms like LIA and MWE for example. We hope to address many of the issues you make in your email - seasonality, consistency of the proxy through time, goodness of the proxy etc. We need to come up with some agreed strategy on this especially with IPCC coming up.

What we did in the paper was one way of assessing proxy quality. Something like Tables 2 and 4 are what is required though to inform the uninitiated (modellers) about proxy data. For use in detection at the moment a paleo series has to be a proxy for temperature. I know proxies tell us about other aspects of the climate as well, but a clear, unambiguous temperature signal is what is needed.

Some other quick answers -

- 1) Happy to send to you all the series and the hemispheric values. I hope Mike will send all his as well, but the last time we discussed this he said that some could not be made freely available. This isn't Mike's fault but there are still some stumbling blocks to free exchange of data within the various paleo communities.
- 2) We all know the quality of proxies changes with time. Trees don't have dating problems but do have the reduction in sample depths you talk about. Dendro people are much more open about this though than the coral and especially the ice core communitites.
- 3) Trees may not grow everywhere but they are more global in extent than the others. There are also many more chronologies available and this is a factor. We had much more choice there than in the other paleo groups.
- 4) Whilst we are taking bets, proxies will never be better than instrumental data. Corals will eventually extend the SOI series but never be better than it for the years after 1850. Similarly with the NAO. Instrumental data exists to extend this to about 1750 and the fact that such data is sitting out there is only just begining to be realised. A great NAO

reconstruction could be produced if the real data extended over nearly 200 years, enabling the low-frequency aspects to be considered in much more detail than ever before (a la Stahle with the SOI).

That's enough for now.

Cheers
Phil

Dear Geoff

it good to hear from you. By now you may know that we had a small working meeting to consider the current draft of the thematic bid yesterday in London. Simon Tett , Nick Shackleton , Paul Valdes and I really did get to grips with a lot of the important details concerning the way in which such a project might actually run. We are going for a joint Earth science/Atmospheric Science Board application for 8 million to run over 5 years. Simon told us about your offer of some support - perhaps as money , perhaps as some equivalent- and the spirit of the offer is much appreciated. Frankly, the fact that you consider this a worthy and valid scientific exercise is what really gives me cheer. We have a long way to go to really sort out many of the problems with the palaeo data and with the methodology of using them in a validation and/or detection context, but I genuinely believe this approach will yield rewards somewhere down the line. I think our support from the earth science side is very probable. The politics of the Atmospheric Board - and the potential clash with other initiatives coming from Reading - mean that their support (in any meaningful sense) can't be thought of as more than possible. I suppose we may have something like a near 50 % chance of eventually getting some money , but 50% is pretty good. I will now ammend the document to show an explicit requirement for formal supervisory input on the programme from the Hadley Centre and I acknowledge that there will be no blanket release of data whatever happens. I will forward the application to you soon. If we get through the outline agreement stage with NERC , we will surely revisit these practical details , along with others. For now I simply say thanks to you and John for your support , and thanks for the input of Simon and Peter Cox. I will stay in touch as and when things develop. Even if we fail here, the science imperative will mean that we find other means of working with you -most likely through an EC grant - on these issues.

Thanks again and I hope you are bearing up under the strain of recent troubles

Keith

Ray

this is simply to say that I will get my paper to you as soon as I can. Frank knows that I am currently involved with writing a bid on behalf of the earth science community to try to extract 8 million pounds for a 5 year project from NERC to support Palaeo/Modelling validation work. I was not allowed to say no to this request and it is involving me in a lot of meetings and associated crap. I am now redrafting the proposal. Also I must write my application to NERC for a fellowship - if this fails Sarah and I are unemployed after December as things stand. God knows there is little chance of success but the application must be in by the end of September and I have not started it yet. This is a big deal for me and I am putting you down as my primary suggested scientific referee. The PAGES paper can only be done in mid October and I really need your and Frank's understanding on this. I had to do the Thematic bid proposal as Nick Shackleton asked me to , and I want to put him down as my primary Personal reference! In early October I have to attend a NERC Earth Science Board meeting to defend the Thematic bid; a meeting of PEP3 in Belgium;a UK CLIVAR meeting in London; an EC meeting to present our ADVANCE-10K results in Vienna. This is not bullshit. I will do the PAGES meeting paper as fast as I can and you must please allow me the leeway . Sorry - but this will not really hold the publication up . If I could sort out some funding I could afford to drop some of these things but with the EC future also up in the air at the moment , I have to try to juggle these things. Sorry again Ray

Keith

Hi Phil - thanks for your detailed reply to my email. I look forward to working with you and the rest of the gang to really improve the state of paleo contributions to the detection/attribution issue. The earlier we get a small group together, the better, so I suggest we try to take you up on the AMS add-on idea. It would be ideal to have a 1 to 1.5day mtg in Boulder since we have many of the needed perspectives (ice core, coral, sed, data, etc) here. What would be the best dates for you (and Keith - I'm hoping he'll be up for this too). We can find the extra \$\$ to get folks to Boulder and have a quality time (do you ski?).

Once we set the dates with you (PLEASE SEND FAVORED DATES), Mike and Ray, we can set the agenda. The main thing is that it would set the stage for the extra degree of data sharing we'll need before the planned Santorini mtg (still no dates - please bug Jean-Claude!!). Sound ok?

As for the data from your paper, I'd like to get them up with the data from the other studies on the WDC www site asap. (JUST LET ME KNOW HOW!) The White House is interested in knowing the state-of-the-art, and if we can get everything together at one www site (including data and figs), I think I can get some needed visibility for the paleo perspective. You probably know this, but Henry Pollack's Borehole view of things (similar conclusions to the other recent papers) is about to appear in Science. Although each proxy and method does have it's limitations and biases, the multiproxy view is compelling with regard to the patterns of temp change over the past several centuries. The IPCC next time around should be much stronger than last on the paleo side of things (although still not as good as it can get!).

Of course, I'll continue to work with Mike and Ray to get the rest of the individual series out into the public domain. Santorini should be the goal - not allowed on the island without coughing up data first!

Aloha and thanks again! Peck

Hi Peck,

Thanks for ccing the message. I was talking to Ed Cook at a NASA workshop we both attended a couple weeks ago, and he also expressed quite a bit of interest in attending the mini-meeting, since he'll be going to the AMS meeting to.

When is the meeting? Do other people prefer just before or just after the meeting for the workshop. Either probably works easily well for me at this point, since I won't have teaching committments at that point.

Looking forward to us finalizing a plan!

mike

Subject: Meeting on SRES Scenarios, 1 October 1998
Date: Thu, 01 Oct 1998 21:57:23 +0200

Dear Colleagues,

A meeting was held today on SRES scenarios during the IPCC plenary session in Vienna. The meeting was organized by David Griggs, Fortunaat Joos, Richard Moss, and Rob Swart. Also present were a number of delegates including two Co-Chairs of IPCC, John Houghton from WGI and Bert Metz from WGIII. Attached is a document with issues discussed during this meeting.

The meeting was very productive in my view, even though it was quite brief. Two key issues were discussed that are listed in the attachment: (1) incomplete information concerning SRES emissions as reported on the website, and (2) consistency and plausibility of SRES scenarios and their emissions.

(1) Incomplete information

There appeared to be a general consensus that the range of CO₂ emissions (especially energy-related ones) are in quite good agreement across the SRES scenarios once one adds the missing emissions categories to all model runs. They are also in a relatively good agreement with the ranges given in SAR.

The SRES ranges of CH₄ and N₂O emissions did not appear to be a problem in themselves, but they are considerably lower than the ranges given in SAR.

It was agreed to ask the SRES writing team to further harmonize the ranges for the base year and the period 1990 to 2000 across the scenarios for CO₂, CH₄ and N₂O. At the same time, David Griggs will contact the colleagues from WGI to inquire whether the emissions ranges for these gases as given in SAR have changed in the mean time and will inform the SRES colleagues soon about the result. In particular, he will check whether the non-energy CO₂, CH₄ and N₂O emissions ranges are still appropriate as best guess for the 1990 situation and about any new numbers about the ranges for more recent years. It was also suggested that the SRES writing team discuss the reasons for relatively low CH₄ emissions in 1990 compared with the SAR range.

Most of the SRES models do not generate CFC and HFC emissions but these emissions are important for climate models. It was agreed that David

Griggs will inquire with climate modelers whether they really need all species of these gases or whether it is sufficient to report their joint emissions. SRES team is to report whether these emissions could be added to most of the model runs and over which time-scale. Joergen Fenhann is in touch with a number of colleagues on this issue already and he is planning to make a specific proposal how to handle this question across SRES scenarios.

SRES sulfur emissions are considerably lower than the IS92 range. There are a number of reasons for this difference that were discussed at the meeting. It was decided that this exchange should continue in the future so that there is a better understanding of all issues involved. This is a new aspect of SRES scenarios that represents an important change since IS92a, a change that was also suggested by the 1994 IPCC review of emissions scenarios.

The concern raised by Hugh Pitcher (in the WGI scenario discussion group) about high productivity growth in A1 scenarios was briefly mentioned. This issue is to be settled within the SRES writing team, possibly by including the formulation of alternative scenario variants.

(2) Consistency and Plausibility

Most participants of the meeting expressed the need to have emissions trajectories that are somehow normalized for all SRES scenarios for 1990 and that have the same trends through 2000 and diverge only thereafter across different scenarios. This would meet the need of climate modelers to work with the same starting points for all scenarios they model. One suggestion was that SRES team simply takes midpoints of emissions ranges in 1990 and renormalizes all SRES emissions. Another proposal is that climate modelers suggest their preferred values for 1990 to be used in renormalization. In any case, the method that is used would need to be well documented and cited in the relevant IPCC reports. This is necessary so as not to introduce an artificial impression that there is a full agreement on base-year emissions across SRES scenarios.

There were no specific suggestions how to harmonize short-term emissions through 2000. This issues is to be discussed within the SRES writing team and within the climate modeling community in order to collect emissions data for the last years that could be used for such harmonization.

The issue was discussed of generally lower CO₂ and SO₂ emissions across the range of SRES scenarios and in particular for B2 marker. This results in

lower GHG forcing and lower "negative" SO2 forcing. The total forcing remains roughly the same as in IS92a but has fundamentally different implications especially at regional level.

Most of the climate models will be in the position to use just a few scenarios, in some case, may be just two. Possible ways of avoiding the impression that there is a "preferred" scenario were discussed and there was a consensus that somehow the message needs to be conveyed that the whole set of SRES scenarios is plausible and that there is really no single "central" case that can be compared with IS92a.

Climate models need gridded SO2 emissions while SRES models generate SO2 emissions for a number world regions. Mike Schlesinger and Steve Smith will attend the next SRES meeting and it was suggested that Mike would use his method to produce gridded SO2 emissions and that Steve would use the method proposed by Tom Wigley to do the same. This way there would be two alternative gridded emissions patterns for all SRES scenarios available to user groups.

In conclusion, it was agreed that it would be useful to organize an informal meeting where SRES colleagues could meet with potential user groups from TAR (especially from WGI and WGII). Next possibility to do so would be on the occasion of the WGI meeting in Paris, 30 November to 3 December. I am not quite sure that I got the dates right. The next communication will be more precise.

Regards, Naki

Subject: INTAS, Vienna and Norwich
Date: Fri Oct 2 10:51:37 1998

Dear Stepan and Eugene (and Fritz),

I have now received contracts from The EC for the INTAS work.

I have received the real signed Power Of Attorney form from Stepan , but not from Eugene.

It seems I must have both . I am a bit reluctant to forge Eugene's signature! We will need to think about how the money should be handled . Also please all go back and look at the document I wrote and be sure you are happy with the commitment. The most important new aspect is the biomass work and I think new , or additional collections need to be taken to look at the growth of young , medium and old trees separately through time. We have very few recent young and middle age trees in recent years. We could consider using data along north/south transects (how goes the status of the Siberian Transect?).

Also, I must go to Vienna in 2 weeks to present the results of ADVANCE10K . We have a meeting of this group here in Norwich in November but I am very sorry that I have no funds to invite you to attend this. Could you afford a meeting some time , perhaps in a neutral spot where we all (including Fritz) might get together to talk about the INTAS work and future EC work? A state of the art report of progress of the Taimyr and Yamal work is needed very soon (by email), also so that I can report on it in Vienna and Norwich. I am also writing a paper for PAGES for the book of the conference in London that Rashit attended. I will include a report of both projects , hopefully with some Figures of the data distribution or plots of the some version of the curves themselves (along with others at high latitudes) . I would appreciate new copies of the full dated raw data sets , in Tucson compact format, to produce some curves in a standard style. I would like to compare changing variance through time at different wave lengths and perhaps co spectra.

As for money on ADVANCE10K, I initially was awarded 50,000ECU to be split between Krasnoyarsk and Ekaterinburg. Because of exchange rate changes , which have gone against us continually since the start of the project, this is now worth between 0.2 and 0.25 LESS than it did then. I have looked at the remaining money and I think I can give you each a final payment of between 4000 and 4500 US dollars. This is not definite - but it is pretty definite! I hope this means you may be able to do this year's fieldwork. We need to think also about how and if this should be coordinated with the INTAS work - but maybe not? How about some discussion by email regarding these points. I look forward to a quick reply.

my best wishes

Keith

Subject: TAR/SRES urgent use scenarios
Date: Sun, 04 Oct 1998 14:17:34 -0700

////////////////////////////////////

Prather's comments on SRES emissions regarding the four WGI chapters on radiative forcing.

THIS ADDRESSES ONLY THE URGENT NEED TO GET THE CLIMATE SCENARIOS STARTED.

OVERALL: It is CRITICAL that the WGI chapters are involved in and make decisions regarding the mapping of "emission scenarios" onto "trace-gas/RF scenarios" (to then be used in generating "climate scenarios"). This is needed so that the eventual chapters will back these preliminary (and hurried) approaches and present a consistent but updated (and more complete!) set of similar RF calculations in the TAR. We should not be adding new "volunteers" to calculate these forcings as has been suggested by last week's notes until we clearly agree on the rules/algorithms..

CO2: (WGI-Ch.3)

I have not heard from colleagues on Ch. 3 regarding carbon-cycle models for these scenarios that would be consistent with their pending chapter..

non-CO2 GASES: (WGI-Ch.4)

We need to make sure that the COMBINATION of adopted "atmospheric chemistry" and emissions is consistent with recent observations. It does not mean the total burden is on emissions. Once having chosen the chemistry (i.e., 120 year "lifetime" for N2O today), however, the current emissions are tied by observations. So we will do as already stated "make emissions match observations" but must be careful in the chapter to note this.

I see no obvious need to change the OH lifetimes (CH4, HFCs) and the N2O lifetimes from the SAR. The debate over a trend in OH is important for later analysis in the chapter. The key here is for consistency with the past decade. The budget of 560 Tg(CH4)/y is thus a balanced (steady-state) budget to match abundances of about 1710 ppb, and the current increase of about 1-2 ppb/y would then add about 3-5 Tg to this amount. Thus the rate of growth of CH4 emissions in the SRES is one concern, but the absolute level in the late 1990s is the most critical.

The IPCC97 Mosier & Kroeze N2O budget stands: natural = 9.0 TgN/y and anthrop = 7.2 TgN/y. Thus ALL of the N2O scenarios need to be scaled. Is this by a time-independent offset (e.g., + 5.5 TgN/y for B2)? or do we multiply the anthropogenic by a constant factor (e.g., 3 for B2)?

HFCs cannot be included as a bulk emission values since their lifetimes are so varied. What could be done is to focus on a single one as a surrogate, e.g., HFC-134a is the dominant RF from the IS92a options calculated in the SAR. Is this still so? We need to look at the projected HFC industry as in the last WMO

report.

O3 - as part of the IPCC/Aviation assessment (under SAR, now in final government review) we spent considerable effort in calculating the changes in O3 and the associated RF. This included both changes due to aircraft alone and that due to increases in CH4, CO, NOx, VOC described in IS92a. The 3-d tropospheric chemistry models generally agreed upon the O3 changes, and it looks as though we shall be able to take the SAR to the next step and predict changes in tropospheric ozone with a community consensus. (The results were only for IS92a 2015 and 2050 atmospheres, RF's not fully analyzed for background, of order 0.2 W/m2 for 2050.)

For the AOGCM scenarios I propose that we use these 2050 delta-O3 scenarios to "deliver" a zonal, annual mean O3 RF as a simple function of latitude. It would be easier that transmitting the perturbed O3 patterns to the AOGCMs and would accomplish the primary goal of including the O3 RF. The IS92a 2050 pattern would be scaled to the amount of NOx emitted and CH4 concentration (maybe). This is probably OK for now, but of course the correlation of NOx and CO emissions in generating O3 and OH changes is "current science" that needs to be evaluated in the chapter. Also the regional aspects of CO and NOx emissions affect the O3 perturbation.

I would PROPOSE that WGI-Ch.4 define the algorithms (e.g., CH4 lifetime @ 1700 ppb plus feedback factor and how to implement it) along with the constraints of the 1990s and then let the SRES scenario builders come up with a consistent set and send these on to the AOGCMs.

SULFUR & other AEROSOLS: (WGI-Ch.5)

The AOGCMs should NOT use their own sulfur cycle for the first of the climate scenarios. There is little doubt that all will produce vastly different negative RFs and hence different regional climate response. As I remember listening to the arguments for preparing these climate scenarios, the PRIMARY goal is to assess how well/consistently we can predict future climate and especially regional changes given a set of forcings. Likewise, we do not want these scenarios generated from different time lines for CO2, CH4, and O3 because the models have different cycle for these gases. So why S? While many of these models may have scientifically excellent S cycles and include indirect impacts on cloud formation, this task (i.e., comparison of S models in GCMs) should be the second tier of experiments.

Given the primary goals of these climate simulations by the AOGCMs, it would seem best to specify a simple albedo/RF by lat-long, ONE THAT Chapter 5 of the new TAR would advocate and support in its chapter. (e.g., what is suggested by Chapter 4 for O3 above) For example, the current geographic pattern of direct sulfate forcing has been studied and will obviously be reviewed/summarized by WGI - Chapter 5; this could be scaled to total S emissions, especially since they are dropping in most of the SRES emission scenarios. It would still provide a basic test of our predictions of regional climate across the AOGCMs.

There is nothing here to develop scenarios for other anthropogenic aerosol forcings that appear to be important (i.e.,

organics and soot).

summary RF: (WGI-Ch.6)

A potential issue here is the ability to de-convolve the
emissions and RFs per sector.

Subject: Re: climate of the last millennia...

Date: Tue, 6 Oct 1998 11:06:20 -0400 (EDT)

Dear all,

I just wanted to thank Keith for his comments. They are right on target. There is indeed, as many of us are aware, at least one key player in the modeling community that has made overly dismissive statements about the value of proxy data as late, because of what might be argued as his/her own naive assessment/analysis of these data. This presents the danger of just the sort of backlash that Keith warns of, and makes all the more pressing the need for more of a community-wide strategizing on our part. I think the workshop in Jan that Peck is hosting will go far in this regard, and I personally am really looking forward to it!

cheers,

mike.

Hi Peck et al.

A little late but I'd like to put in my twopence worth regarding your original message and Phil's reply. I have been tied up with a load of stuff so don't interpret my lack of speedy response as a lack of interest in these matters.

My first comment is that I agree with all of your general remarks and with your implied rebuke to Phil that we should be very wary of seeming to dam certain proxies and over hype others when we all know that there are real strengths and weaknesses associated with them all. The truth is that all of this group are well aware of this and of the associated fact that even within each of these sub-disciplines e.g. Dendro, coral etc. there is a large range of value, or concern with the external usage of our data. However, my own and Phil's concerns are motivated, like yourself, by the outside world's inability to appreciate these points and the danger that we will all be seen as uncritical or naive about the real value of proxy data. The rationale for the recent Jones et al paper, and some things that I have written in the past is to inform would be users, particularly the modellers, that there are critical questions to be addressed about how the palaeo-data are best used in a 'detection' or 'model validation' context. Many in the palaeo-community understand these issues, but perhaps there has been some reluctance to air them in sufficient depth or in the right situations where they will be heard/seen by those people who now seek to use the data. I believe that many of the modellers, having been blissfully unaware for years of the need to work with the palaeo-community, are now expecting too much. This carries the danger of a backlash as they undertake simple assessments of the palaeo-series and conclude that they are all of very little use. The problem is that as we try to inform them we may get the balance between valueable self criticism and scientific flagellation wrong. The more so when the whip is seemingly aimed at others!

There is no doubt though, that many palaeo- types are not concerned with the 'bigger issues' of climate change, so it is up to those who do, such as this group, to try to sort out some sensible approach to how we do explore the good and bad, fairly, in our collective data and how we present this to the outside world. The meeting you propose is a good way forward. If he is already not included, I also urge you to invite Ed Cook.

I hate cold feet and I don't ski so I vote for anywhere away from snow.

To answer the question about the degradation in tree-ring chronology confidence back in time - yes, we (that is several of us in tree rings, and rising out of them, in average temperature or rainfall series, have

suggested a basis for quantifying chronology error as a function of series replication and time-dependent changes in the correlations of the series that go to form the mean chronology. The problem is tricky because the error is timescale (i.e frequency) dependent also. This is just the chronology. Calculating confidence limits on reconstructions derived from one or more chronologies must take account of the regression error (again likely to be timescale dependent) while incorporating the additional uncertainty associated with the chronology. When the reconstructions are derived using a spatial transfer function (such as in canonical correlation or our similar Orthogonal Spatial Regression technique)the reconstruction at each point in the predictand network has some ,different, uncertainty relating to the error in each predictor series and the magnitude of its influence in the specific regression equation relating to that point. Finally, as regards this issue, if you have detrended or high-pass filtered the original predictor series in some way (i.e. tree-ring standardisation) , you have some potential long-timescale uncertainty around the final reconstruction which can not be represented by any analyses of the remaining predictors or their association with a relatively short instrumental predictand series. I have a half drafted paper on this which I intended to submit to Tree-Ring Bulletin - perhaps one day!

Your question about Jasper, the sample depth, in my opinion , IS responsible for the early high values. So don't put much faith in the early warmth. We have devised a simple method of scaling down the variance in average series to take account of the inflated variance that occurs when a reduced number of series are averaged - such as at the start of this chronology . We used this in our recent Nature paper looking at a possible volcanic signal in the density data averaged over the northern network. Ed has incorporated this in the latest version of his super tree-ring standardisation/chronology construction program , but it was not used in the Jasper work .

I agree that we must be careful not to appear to be knocking other proxies- even if this is not intended . We must also be explicit about where problems lie and in suggesting the ways to overcome them. I for one do not think the world revolves only around trees. The only sensible way forward is through interpretation of multiple proxies and we need much more work comparing and reconciling the different evidence they hold. Let's have more balance in the literature and more constructive dialogue /debate between ourselves.

Keith

From: Rashit Hantemirov <rashit@ipae.uran.ru>
To: Keith Briffa <k.briffa@uea.ac.uk>
Subject: Short report on progress in Yamal work
Date: Fri, 9 Oct 1998 19:17:12 +0500
Reply-to: Rashit Hantemirov <rashit@ipae.uran.ru>

Dear Keith,

I apologize for delay with reply. Below is short information about state of Yamal work.

Samples from 2,172 subfossil larches (appr. 95% of all samples), spruces (5%) and birches (solitary finding) have been collected within a region centered on about 67030'N, 70000'E at the southern part of Yamal Peninsula. All of them have been measured.

Success has already been achieved in developing a continuous larch ring-width chronology extending from the present back to 4999 BC. My version of chronology (individual series indexed by corridor method) attached (file "yamal.gnr"). I could guarantee today that last 4600-years interval (2600 BC - 1996 AD) of chronology is reliable. Earlier data (5000 BC - 2600 BC) are needed to be examined more properly.

Using this chronology 1074 subfossil trees have been dated. Temporal distribution of trees is attached (file "number"). Unfortunately, I can't sign with confidence the belonging to certain species (larch or spruce) of each tree at present.

Ring width data of 539 dated subfossil trees and 17 living larches are attached (file "yamal.rwm"). Some samples measured on 2 or more radii. First letter means species (l- larch, p- spruce, _ - uncertain), last cipher - radius. These series are examined for missing rings. If you need all the dated individual series I can send the rest of data, but the others are don't corrected as regards to missing rings.

Residuary 1098 subfossil trees don't dated as yet. More than 200 of them have less than 60 rings, dating of such samples often is not confident. Great part undated wood remnants most likely older than 7000 years.

Some results (I think, the temperature reconstruction you will done

better than me):

Millennium-scale changes of interannual tree growth variability have been discovered. There were periods of low (5000-2800 BC), middle (2800-1700 BC) and high interannual variability (1700 BC - to the present).

Exact dating of hundreds of subfossil trees gave a chance to clear up the temporal distribution of trees abundance, age structure, frequency of trees deaths and appearances during last seven millennia.

Assessment of polar tree line changes has been carried out by mapping of dated subfossil trees.

According to reconstructions most favorable conditions for tree growth have been marked during 5000-1700 BC. At that time position of tree line was far northward of recent one.

[Unfortunately, region of our research don't include the whole area where trees grew during the Holocene. We can maintain that before 1700 BC tree line was northward of our research area. We have only 3 dated remnants of trees from Yuribey River sampled by our colleagues (70 km to the north from recent polar tree line) that grew during 4200-4016 and 3330-2986 BC.]

This period is pointed out by low interannual variability of tree growth and high trees abundance discontinued, however, by several short (50-100 years) unfavorable periods, most significant of them dated about 4060-3990 BC. Since about 2800 BC gradual worsening of tree growth condition has begun. Significant shift of the polar tree line to the south have been fixed between 1700 and 1600 BC. At the same time interannual tree growth variability increased appreciably. During last 3600 years most of reconstructed indices have been varying not so very significant. Tree line has been shifting within 3-5 km near recent one. Low abundance of trees has been fixed during 1410-1250 BC and 500-350 BC. Relatively high number of trees has been noted during 750-1450 AD.

There are no evidences of moving polar timberline to the north during last century.

Please, let me know if you need more data or detailed report.

Best regards,
Rashit Hantemirov

Dear Keith,
below is the list of publications concerning Yamal chronology.

References of russian articles are in three forms:

- a) original russian text. I am afraid you will be not able to read (see) it without any russian driver. Therefore, if you need this form of reference, please see attached file as well (.doc file) using attached russian font;
- b) russian words written by english letters;
- c) english translation (excuse me for my english).

Shiyatov S.G., Hantemirov R.M. Dendrochronological dating of shrubs wood from archeological settlement "Yarte-6" on the Yamal Peninsula // Antiquities of Yamal. Tobolsk, 1998 (in press).

I am not quite get your question about fieldwork. You mean "this year" is 1998? If so it is too late now, on southern part of Yamal yesterday was about -10 C. Next year we plane fieldwork, final decision about where and when we will make in the beginning of next year. I would like to go to Yuribey River, northward of our usual research area.

From: Sarah Raper <s.raper@uea.ac.uk>
To: scenarios@meto.gov.uk
Subject: Scenarios Conference - Simple Models
Date: Wed, 14 Oct 1998 13:25:07 +0100

3. Use of simple climate models

3.1 Simple models used only as tools for extrapolation/interpolation GCM results to estimate the effect of different scenarios or sensitivities?

1-D UD/EBMs (upwelling-diffusion energy balance models), such as the Wigley and Raper (1992) model updated in Raper et al. (1996), in my opinion, come into this category. I along with Jonathan Gregory and Tim Osborn have completed a very detailed comparison of this and several alternative 1-D models with HadCM2 results. With the addition of a sea ice parameter the Raper et al. model reproduces well the HadCM2 results for global mean surface temperature and thermal expansion out to 2100, for several scenarios.

However, the distinction between 3.1 and 3.2 below is not clearcut. By the end of the 900 year 2xCO₂ experiment the thermal expansion for the HadCM2 model is nearly 5 times larger than that simulated by the fitted (over 1860-2100) UD/EBM, and unlike the UD/EBM shows no sign of coming to equilibrium. In our analysis we conclude that it is not immediately obvious which if either model is correct. The difference serves to highlight the uncertainty in the thermal expansion commitment. Incidentally a fitted pure diffusion/EBM gives good simulation of the HadCM2 results in both the short and long term.

3.2 Simple models used to offer independent climate predictions?

It would probably be difficult to use 2+D models for 3.1, so they may belong here.

I think, 3.1 and 3.2 serve different purposes. Both may be desirable.

3.3 Depending on the answers to 3.1 and 3.2.....

Whichever 3.1, 3.2 or both is adopted the results and the attendant simple model versus A/OGCM comparisons should be given in the projections chapter. A selection of the results should then carry over to the sea level chapter. This consistency is very important.

It is a separate question as to whether the simple climate model results should subsequently be used as scaling factors for regional scenario development in the scenario chapter.

3.4 How many simple climate models are needed...

For 3.1 in order to fit the A/OGCM results extensive comparisons using alternative parameter values/models (for example, UD versus pure diffusion) will be necessary. As well as my HadCM2 comparison mentioned above a comparison with ECHAM3/LSG results is also well underway. In both cases the work shows that it is advisable to calculate the effective climate sensitivity of the A/OGCMs for use in the simple model. We found that the effective climate sensitivity is non-constant but apparently varies with the surface temperature in these models. For this calculation and for comprehensive model comparisons a specific list of A/OGCM output is required. This includes decade ocean mean temperature profiles, a measure of the strength of the thermohaline circulation, the A/OGCM forcing change for 2xCO2 etc. I am keen to continue these comparisons specifically as input to the new IPCC assessments. Unfortunately, and I think mistakenly, the US DOE have recently decided to discontinue this line of research. An endorsement of the need for this work by the IPCC would help my attempts to acquire funding elsewhere.

For 3.2 there would be no need of tuning to A/OGCM results and many model results could be used to give a range. This would serve a different purpose to 3.1 where A/OGCM results are interpolated/extrapolated for different sensitivities and forcings.

> 3.3 Depending on the answers to 3.1 and 3.2, where will
> the assessment of simple model results be located within the TAR (under the
> projections or the scenarios Chapter or under an Appendix?)

> 3.4 How many simple climate models are needed (again
> depending on 3.1 and 3.2)?

I wish to pick up on two of the points raised by Sarah Raper and Jonathan Gregory which, while not directly answering the questions posed above, need a clear position being taken upon by IPCC. These two points are:

>From Gregory

"The presentation of a wide range of scenarios and sensitivities (3.1) will be a very important output of the TAR. Tom Wigley argues that it would be inappropriate to relegate it to an Appendix. Nonetheless it is different from the discussion and assessment of models which produce the basic projections of climate change and sea-level. I think both climate change and sea-level chapters should have separate, final, sections devoted specifically to showing the full range of uncertainties and the best estimates - an appendix to each chapter. The figures given there will be brought together in the summary of the TAR."

This is a very important concern from the perspective of how Chapter 13 (climate scenarios) is written and how WGII will look over their shoulder to WGI. For many reasons which have been well-articulated elsewhere, it is too much to expect complete consistency from WGIII emissions, to WGI models and to WGII impacts - the lags in the knowledge creation and ratification are too great. However, bear in mind that most GCM results used for climate scenario construction will be 1% per annum forcing (plus a few with 0.5% forcing, stabilisation forcing or one or more of the new SRES forcings, but these latter GCM results are unlikely to feed forward into (much) impacts work in time). However, for much impacts work to be

properly assessed and interpreted by IPCC it is necessary to have used a range of climate scenarios spanning a range of risk. This is difficult, nay impossible, without resorting to simple climate model results. If WGI can Fast-track this generation of headline projections spanning a range of forcings and sensitivities, then this information may be made use of by climate scenario developers and impacts analysts. If not, then WGI (Chapters 9 and 11) will be saying one thing, and all the impacts work is in danger of saying something else (e.g. using IS92 forcings with the SAR Chapter 6 simple model projections). At worst, some careful post-hoc re-interpretation of WGII results may be necessary in light of WGI for the policymakers summary and most importantly for the Synthesis Report.

>From Raper

"It is a separate question as to whether the simple climate model results should subsequently be used as scaling factors for regional scenario development in the scenario chapter."

This is indeed a separate question and one on which Chapter 13 can and will 'assess' the science. Scaling of GCM results has been widely used by impacts/integrated assessors since CRU started using this methodology in the early 1990s. Whether or not to adopt/recommend scaling methods for the IPCC TAR was side-stepped by the TGCIA, although it was clearly stated within the TGCIA that basing all impacts work on 1% p.a. forced GCMs which represented a narrow range of climate sensitivities, would skew impacts results in a particular (and not altogether desirable) direction. Chapter 13 will also recognise this problem and will assess the pros and cons of scaling based on simple models, but given the short length of Chapter 13, its remit now is not to convert any headline simple model results from Chapters 9 and 11 into scaled regional scenarios for impacts work - by mid-late 1999 it will be too late for that anyway. So, different impact studies will now adopt different approaches, and WGII can assess the resulting science, but what will help the writing of Chapter 13 and WGII will be as clear a statement of intent (and ideally some preliminary results) of the sort of exercises that Sarah and Jonathan refer to, preferably using the new SRES emissions scenarios.

Draft manuscript

VARIABILITY OF LARCH RADIAL GROWTH IN THE EAST OF TAYMIR AND PUTORAN FOR THE LAST 2000 YEARS

M.M.Naurzbaev, E.A.Vaganov

Taymir Biospheric Reserve, Khatanga

Institute of Forest, Krasnoyarsk

Abstract

Regional tree-ring chronology with extension 2209 years (since 212 B.C. till 1996 A.D.) was built for the east of Taymir according to wood of living trees, well preserved residues of dead trees and semi-fossil wood from alluvial bank deposits by the cross-dating method. In addition the "floating" tree-ring width chronology for the period of Holocene Optimum (3300-2600 B.C.) was built with extension 685 years and supported by several radiocarbon dates. High values of synchrony and correlation of individual tree-ring series show a prevailing effect of one external factor on radial tree growth change in the studied region of Siberian subarctic. It was established that the main factor of growth variability the early summer and annual temperature is which explains up to 70% of tree growth rate variability. Cyclic components stable for two millennia were revealed at analysis of the tree-ring chronology: double secular (about 180 years), secular (78-90) and intrasecular (44, 28, 11 and 6,7-6,9 years) variations. Models for reconstruction of the early summer and annual air temperature were obtained according to tree growth variability. Temperature dynamics in the eastern part of Taymir for the last two millenia agrees well with temperature variations in the northern hemisphere obtained according to other indirect sources. The warming of the middle of the 20-th century is not extraordinary. The more long in time, and close in amplitude the warming at the border of the first and the second millennia was.

Key words: radial growth, tree-ring chronologies, temperature change, dendrochronology, climate, growth cyclicality, temperature reconstruction, response functions.

Introduction

The leading dendrochronological groups began their work in some key regions of circumpolar zone of the northern hemisphere

on building the superlong (several millennia, and for the whole Holocene period if to use subfossil wood) tree-ring chronologies for the quantitative reconstruction of natural temperature variations [6,8,19,20,35,36]. The high latitudinal regions in the northern hemisphere are of greatest interest for assessing natural and anthropogenic variations of air temperature, forest-tundra ecosystem growth and productivity, regeneration regime as well as of polar timberline dynamics because the ecosystems of high latitudes have the highest sensibility to the expected global climate warming [4,15,18,19,22,43]. Owing to accessibility and great amount of well-preserved wood of dead trees as well as of subfossil wood from alluvial river deposits and wood buried in bogs several regions in high latitudes of Russia turned to be promising for building millennial chronologies: the Polar Urals [15,31], Yamal peninsula [32], the east of Taymir and Putoran [7,8,14] and the lower Indigirka river[34]. The following problems were solved in the given paper: 1) obtaining of the absolutely dated 2000 year tree-ring chronology suitable for quantitative reconstruction of climate changes; 2) revealing of the main climatic factor responsible for the year-to-year and long -term growth variability; 3) building of models of climate change reconstruction for the whole period of long tree-ring chronology.

Material and methods

Dendrochronological material was collected in Kheta-Khatanga plain as well as in Moyero-Kotuy plateau regions of the Middle-Siberian forest zone within the northern stripe of the northern taiga subzone [1] (Fig.1). The wood samples were taken with the help of a borer or chainsaw from the living trees, from the well preserved residues of a dead and subfossil wood. The whole sampled material is from trees from three types of conditions: 1) from the contemporary northern timberline of larch in the stow (urotchishche) Ary-Mas of the Taymir biospheric reservation (latitude of 72 28' N.); 2) from contemporary upper timberline with absolute marks 200-300 m above sea level in the Kotuy river valley (latitude of 70 30'-71 00' N.); 3) from alluvial deposits of flood-land and over-flood-land terraces of large tributaries of the Khatanga river (latitude of 70 30'- 73 00'N.). Measuring of the tree-ring width was made with the help of automatized devices with resolution up to 0.001 mm, and later the measured individual tree-ring chronologies were treated in the standard software package for dendrochronological and dendroclimatological analysis [26,33]. Owing to the high year-to-year variability, high

synchrony of individual series between each other the results of the cross dating gave a chance to build the continuous chronology since the year 212 B.C. till 1996 A.D., it means the total length 2209 years. Besides, according to the well-cross-dated discs of subfossil wood for which the series of radiocarbon dates was made at the University of Bern (Switzerland) and at the Joint Institute of Geology, Geophysics and Mineralogy SB RAS (Novosibirsk) the "flooding" chronology of 685 years long was obtained which according to the dates agreed with climatic optimum of the Holocene (3300-2600 years B.C.).

Standardization method is used to treat individual series for the best revealing of climatic signal. This method is intended to remove the changes caused by age or by factors of the non-climatic nature (for example, effect of phytocoenotic factors) from tree-ring width variability. For standardization two approaches were used: 1) an approximating curve of age variations is tried for every individual series [15,26]; 2) an age curve is used which is built according to the entire totality of analysed individual curves of growth [3,11,21,23]. As the special studies showed, the long climatic changes (or super-secular variations) remain more reliably at the second standardization method [21]. Therefore, it was chosen for standardization of individual series and obtaining of the long chronology of tree-ring indexes. Obtaining of regional tree-ring chronology (C1) and of the so-called "residual" series (C2), from which autocorrelation was removed [26,40], was as a result of individual series standardization. The main statistic characteristics were calculated for the obtained chronologies: inter-series coefficient of correlation (as an index of synchrony of individual series), sensitivity coefficient, standard deviation, 1-st order autocorrelation etc.[30,41].

Analysis of the frequency-temporal structure of obtained chronologies at the entire period and at the 500-year intervals was carried out by Fourier method of direct transforming (Blackman-Tyuki method) and Fourier method of "fast or inverse transforming" (Kuli-Tyuki method) [10]. The methods of graphical assessment of smoothed curves [15,16], analysis of autocorrelational function [2,15], a narrow-striped filtering of series [12] were used at the revealing of long (super-secular) cycles in growth variability. Revealing of the main climatic factors of growth variability was based on response function assessing and interpreting [30,42]. The quantitative reconstruction of climatic factors according to variability of growth indexes was made on the base of calculated regression model

at which building one part of climatic series was used for calibration, another part - for verification [6,7,41]. Adequacy of reconstruction model was assessed by standard statistic indexes: correlation coefficient, Fisher's criterion, autocorrelation of residues - criterion of Darbin-Watson [17].

Results

In the result of the cross dating (its quality was checked by statistic estimates according to the COFECHA program [26,33]) of *Larix gmelini* living trees and trees dead long ago from the upper timberline as well as of subfossil wood from alluvial deposits the regional tree-ring chronology since the year 212 B.C. till 1996 A.D. was built for the eastern part of Taymir and Putoran. The total number of wood samples being dated was 118, including 27 living and 91 dead trees. The average age of the used trees made 300 years, the maximum age was 798 years. The percentage of the missing rings is not very large - only 0,5% because the discs were analysed, mainly, but not wood cores [44]. The tree number in the regional chronology is not homogeneous in calendar scale and has a tendency to decrease when moving to the past: 3 and more models since the year 135 B.C., 5 and more models since the year 81 B.C. Dating of dead trees showed that in the upper timberline under continental climate the dead tree residues can remain on the day surface during more than 1900 years. Inter-series correlation coefficient for the whole time period is rather higher than the threshold value (0,62- 0,75, $p < 0,01$). It confirms a stable and strong external influence which synchronizes growth variability of individual trees.

The main statistic C1 chronology for the whole period and in 500- year intervals are given in the Table 1. The high and close coefficient values of sensitivity and standard deviation for the different time intervals show that tree growth variability under these conditions is controlled by one and the same factor during two millennia. Autocorrelation of the first order which shows the growth effect of the previous year on the growth in the next year is of great importance as well. Autocorrelation is not significant after treating it by autoregression model in C2. The average tree-ring width for two thousand years is at the level 0,28 mm but it greatly varies in time, the average tree-ring width is more high (0,40 mm) for the Holocene optimum period (Fig.3). Radiocarbon datings agree well with absolute dendrochronological data.

Analysis of spectral density allowed to show the frequency

stripes important by their contribution to the total growth variability and to assess their amplitude (Table 2). The contribution of millennial cyclic component makes about 4%. The large contribution is brought by double secular cycle (in frequency stripe of 120-220 years) up to 20,6% and secular cycle (in frequency stripe of 60-120 years) - up to 13,3%. The cross-spectral analysis of the 500 year old fragments of chronology showed that during two millennia the double secular (180 years), secular (78-90 years) and several intrasecular (44,28,11 6,7- 6,9 years) cycles are steadily present. Hereat, re-distribution in the capacity of separate cyclic components is observed. Such a re-distribution was already noted in the papers on dendroclimatic data from boreal taiga forests and forest-tundra regions [2,12,15]. Positive anomalies of growth, the most strong in amplitude and long in time, fall on the 4-th century, the border of the 6-th and 7-th centuries, the border of the 1-st and 2-nd millennia, the middle of the 20-th century. However, the negative anomalies fall on the 1-st century, the border of the 13-th and 14-th centuries and the first half of the 19-th century. These anomalies can be explained by superposition of cycles of different length. So, growth increase in the middle of the 20-th century agreed with positive periods of the double secular, secular, and several intrasecular cycles (44, 11, and 6,7 years).

Since at the polar timberline the summer temperature is the main factor of growth limiting [6, 15,35,43], then the dendroclimatic analysis of relation of growth variability was carried out, first of all, with air temperature data for summer period. However, some changes were brought to the traditional searching scheme of correlation with average monthly temperature data. In order to reveal the key interval of the season when temperature mainly affected on radial tree growth the value of correlation coefficient between C2 growth indexes and air temperature for every five days beginning from the 8-th of May was calculated. Everyday data of the Khatanga meteorological station since 1933 to 1989 were used. All the calculations are given in the Fig.4. As we see, the significant positive connection ($p < 0,01$) between air temperature for every five days and growth indexes is observed for the period since June 17 to July 11 and it falls on the interval of stable temperature rise in the season. The temperature of the more late intervals of the season does not show large connection with growth variations. The temperature for the period June 17 -July 11 we called as an early summer temperature. Temperature sum for this time period

shows the most correlation with C2 tree-ring indices ($R=0,77$). Thus, variability of C2 tree-ring indexes is determined by the early summer temperature variability in the east of Taymir and Putoran by 60%. The smoothed (the 5-year moving average) C1 tree-ring indexes and instrumental values of average annual air temperature show high agreement too ($R=0,72$). At the same time the smoothed annual temperature shows the significant relationship with the concordance coefficient calculated for the same period of 5 years based on all wood samples available. This relationship is positive ($R=0.44, p<0.01$) and shows that in cool periods the synchrony in tree-ring variations among all trees measured becomes lower, in warm periods it becomes higher, but has a non-significant relation to tree-ring width variations. Therefore, at searching of quantitative models of reconstruction of leading climatic variables using tree-ring chronologies it was conventionally taken to use C2 for the early summer temperature reconstruction, and C1 - for the annual temperature reconstruction.

The results of calibration and verification of obtained models of the early summer and average annual temperature reconstruction according to 2000-year chronologies data are given in the Table 3 and in the Fig.5. As we can see, the early summer temperature variability is well explained by tree-ring indexes variability in C2 ($R^2 = 0,59 - 0,72$), the average annual temperature variability is described by the model with two variables: by smoothed values of tree-ring indexes in C1 and by concordance coefficient values between individual series ($R^2 = 0,67$) (Fig.5). Comparison of calculated values of the early summer and average annual temperatures with the real ones for the period of instrumental observations shows (Fig.5) that the calculated values of the early summer temperature agree well with the year-to-year variability of real values repeating the most large positive (1940-41, 1953, 1967, 1979, 1984) and negative (1947, 1949, 1980, 1989) extremes. Hereat, in the curves of the early summer temperature variability the long fluctuations are not expressed. To the contrary, the periods of large temperature rise (1938-1956, 1983-1989) and temperature fall (the end of (19)50s and (19)70s clearly agree in reconstructed and real values of average annual temperature.

Based on the obtained models according to two chronologies the reconstruction of the early summer and average annual air temperature was made for the east of Taymir and Putoran for the period since the year 81 B.C. to the present time (it means, for the period provided

by 5 and more samples). The curves of variability of the reconstructed early summer temperature (smoothed by the 5-year and 57-year moving average) are given in the Fig.6. The average value of the early summer temperature equals to 9,6 C for the instrumental observation period. The most large fall of the early summer temperature is marked in the 1-st century ($T=8,4$ C), and in the end of the 13-th century (8,4 C). The most warm periods with the raised average early summer temperature are the end of the 3-rd century ($T=9,7$ C), the border of two millennia (9,6 C), the middle of the 20-th century (9,9 C). The middle of the 20-th century is characterized by the most rise of the early summer temperature, but the 11-th and 12-th centuries are characterized by the long period with high early summer temperatures.

Long variations of the average annual temperature range from minus 14 C to minus 12,5 C. It was of great interest for average annual temperature to compare the reconstruction data with other indirect data on dynamics of average annual air temperature of the northern hemisphere in order to make clear whether temperature variations in the east of Taymir and Putoran reflect global temperature changes in the northern hemisphere. As such the data on reconstruction of temperature variation in high latitudes according to ratio of oxygen isotopes in ice cores of Greenland were used [25,29]. In the Fig.7 both reconstructions are matched in the calendar scale since the late of the 12-th century. Their good agreement is well seen, especially in positive (the 14-th and 15-th centuries, the end of the 18-th and the middle of the 20-th centuries) and in negative (the late of the 13-th and of the 17-th centuries, and the first half of the 19-th) extremes. It means, the long fluctuations of average annual temperature in the east of Taymir and Putoran agree well with global air temperature variations of the northern hemisphere for the last millennium, and hence the tree-ring chrnology of this region can be used to analyse both regional peculiarities and global temperature variations in the northern hemisphere.

Discussion and conclusions

The results of analysis of the super-long tree-ring chronology of the Taymir and Putoran east show that the information on the main climate changes in the northern hemisphere for the last 2000 years is reliably fixed in it: fall of temperature in the first century, climate warming in the 3-rd and 4-th centuries, warming in the Medieval Warm Period (?) or "the small climatic optimum" at the border of two millennia, the long fall of temperature in the 17-th and

19-th centuries ("the small glacial period") and the present climate warming in the middle of the 20-th century [27]. Since the obtained regional chronology has good correlations with other chronologies of subarctic zone within 500- 600 km [6,43], then we can believe that similar regularities of the early summer and average annual temperature variability are typical of large sector of Siberian subarctic. It was shown earlier that the long growth variations agree well for the entire Siberian subarctic [8,24]. The studied region (and this is shown by subfossil wood samples and by obtained "floating" chronology) has a high potential to build the tree-ring chronology for the whole Holocene period and to study in details temperature variations for this period of the Earth history.

Two important consequences from reconstruction analysis should be noted especially. First, the analysis of frequency structure of series and of their separate fragments illustrates a constancy of the main environmental factors limiting growth. It is confirmed also by comparing reconstructions with other indirect evidences. Second, the warming in the middle of the 20-th century, marked as extraordinary [22], has the analogs in the past. So, the warming at the border of millennia shows a close amplitude and was more long [27,38]. Historical evidences on climate of this Medieval Warm period say about the more large climate warming than the present one [13]. The obtained data demonstrate that temperature variations in high latitudes for the instrumental period (1850- 1990) do not go far beyond limits of natural variations revealed during two millennia.

Ratio of natural and anthropogenic components in the present and future climate changes is especially discussed. It is proved in some papers based on the long tree-ring chronologies of North America that the influence of anthropogenic component becomes large and can be separated and assessed quantitatively [39]. Hereat, the trees growing above the upper or polar timberline reflect stable temperature rise in the northern hemisphere [28,35,37]. However, a direct correlation between temperature and growth is marked only for trees from growth regime especially chosen [36,37]. The stable trend of summer and especially winter temperatures for the last decades is connected with the increase of anthropogenic component share, mainly, at the expense of atmospheric green-house gases [4]. At the same time, on large areas of high latitudes (mainly, in subarctic zone) tree growth, correlating well with temperature rise till (19)60s, begins to stunt after this period from the rise of temperature [24]. We can believe that the direct

temperature effect is combined with other factors which influence growth rate of trees in polar latitudes. For instance, increase of winter precipitation can shift the dates of snow cover melting to the more late time even at summer temperature rise [9]. In polar latitudes the conditions of the first season half play the leading role in radial tree growth and tree-ring forming [5,6]. Therefore, tree growth response at the polar timberline will be more complex than we can expect only from summer temperature variations.

Conclusions

1. The long 2209-year (since the year 212 B.C. till 1996 A.D) regional tree-ring chronology was obtained for the east of Taymir and Putoran, suitable for quantitative dendroclimatic analysis and climate change reconstruction. Numerous radiocarbon data of sub-fossil wood and several built "floating" chronologies show a high potential of dendrochronological material of the given region for the building of absolute tree-ring chronology for the main Holocene period (more than 6000 years).
2. The main factors were established which determined the year-to-year variability as well as long-term variability of larch growth in the study region. They are the early summer and average annual air temperature and they determine up to 70% of the total growth variability.
3. In long-term growth variability during two millennia the millennial, the double secular and secular cycles as well as some intrasecular cycles which are met the most often in tree growth variability in polar latitudes of the northern hemisphere are steadily seen. The most large warmings and falls of temperature can be explained by matching particular cycles.
4. Reconstruction of the early summer and average annual temperature variations in the east of Taymir and Putoran showed good agreement of temperature variations in the given region with temperature variations in the northern hemisphere obtained in other indirect sources. The warming in the middle of the 20-th century is not extraordinary. The warming at the border of the 1-st and 2-nd millennia was more long in time and similar in amplitude.

Eugene

I am told that the money transfer (5000 u.s. dollars) should have gone to the bank account you stated. Please let me know if this is received by you. I now also have the contract signed by INTAS and we must organise future work and I will talk to Fritz about us visiting Ekaterinburg next year. In the meantime I wish you and Stepan to organise major review papers of the Yamal and Taimyr long chronology staus for inclusion in the Holocene ADVANCE-10K Special Issue. These need to be completed by June at the latest . They will each be 10-12 pages of print. I can suggest content, do some analyses and help with editing these . I am also sending Stepan's 5000 dollars to Switzerland now to be carried back by his colleague. I have yet to sort out how claims on the INTAS money will be handled. Have you received the details of the final contract?

best wishes
Keith

Paul and Nick

at this point it would be unwise to consider the proposal dead. Yes

it has received mixed receptions in different quarters but this was always to be expected. Each of the boards has its own family to protect , or at least this is the way science funding is now perceived, so that the only consideration in the discussion (especially of proposals from alien boards) is whether or not there will be enough on the carcass for ones own. The strength of our proposal lies in the potential for true cross-Board participation and the real scientific and strategic advantage of the focus on the Hadley Centre work. In my mind the problem has always been to get real enthusiasm from ASTB , and if COAPPEC had not been on the table this may have been more forthcoming. I can not see that we could have done anything more in the circumstances to overcome this hurdle than by enlisting Hadley Centre support. The decision to go jointly only with ESTB and ASTB was already made. The issue of 'no money anyway ' typifies the unsatisfactory nature of the system - but in this case I hear things may not be so bleak. Apparently some millions more pounds are now available than was the case earlier! At this point NERC will say nothing - but they are equally not saying ' sorry and goodbye' . Let us wait and reconsider when we hear something definite.

Incidentally, I have seen a copy of a project funded in Germany where they have millions of marks to compare model and palaeodata to verify and otherwise explore the natural variability in the Hamburg model! They are looking forward to using our data in this exercise!

I will be in touch as soon as I hear more.

best wishes

Keith

Frank is correct in that we need to define 'abrupt climatic change' or even just 'climate change.'

Using Jim's Schulman Grove example suppose that the area supported a stand of bristlecone pine 9,000 or more years ago, hence the scattered remnants. Either a major catastrophic event or a fluctuation in climate (call it climate change if you want) resulted in conditions that killed the mature trees and eliminated any further recruitment for up to 1,000 years. This site may be near the limits of recruitment and with a major (or minor perhaps) change in climate it could easily be beyond the limits of recruitment. About 8,000 years ago climate again became favorable for bristlecone pine recruitment and a new stand(s) developed and have existed ever since. Some or most of the material remaining from the original stand may be buried down in the valley, or the original stand may have been small or sparse. The amount of time between the loss of the original stand and the beginning of the new stand would depend on the period of unfavorable weather and the amount of time needed for bristlecone pine to re-invade the area. I am out on a limb here, so to speak, as I am somewhat ignorant of prehistoric climate patterns for the area and of bristlecone pine ecology, but this seems like a relatively reasonable scenario.

I guess that my point is that climate continues to fluctuate within broad bounds. Everything that we are now calling 'climate change' is well within the bounds observed within the prehistoric record of climate fluctuations. Do we call any variation 'climate change' or should we limit the term climate change for anything considered to be caused by humans? To my mind it is not so much what we call it, but rather that we keep a clear idea of what we actually talking about.

Dear All --

On Mon, 14 Dec 1998, Barrie Pittock wrote:

- > 1. Two issues are being addressed and partially confused:
- > (a) the confidence we have in the science (which seems to be the main concern of the paper);
- > (b) the quantitative uncertainty regarding specific results such as: by what percentage will the rainfall change at 2050 in region/location A? or, how much will changes in tropical cyclones cost in percent of GNP (or additional? lives lost)? My reading of the comments from WG1 authors reported by Neil Leary was that they were focussing more on (a), whereas WG2 authors may want to focus a bit more on (b).

I wholeheartedly agree. While I agree with the probabilistic approach in general, there are a number of practical factors that will mitigate against it. Barrie has listed most, I have added one below.

- > 2. Authors will be limited largely by what is in the literature, especially on the second class of uncertainty. So the guidance needs to go from the authors, or IPCC in some other way (as soon as possible), to the researchers to encourage greater attention to quantifying their uncertainties, and to the authors to put their fingers on misleadingly "precise" estimates by pointing out the basis of such estimates, eg., "this estimated crop yield change is based on only one simulation with one GCM and should be considered in the light of the range of results from other GCMs and for other realisations".

Another source of uncertainty is the different methods used to derive climate change scenarios at regional and local scales. Some authors apply perturbations (based on changes indicated by several GCMs) to historical climate series, some use results from limited area models, while others use one of a wide variety of stochastic approaches that are based on results from one or more GCMs. The important point here is these methods would produce different estimates of uncertainty for the same region and

the same suite of GCMs.

This could be investigated and quantified in a Bayesian framework.

> 7. I share Martin Manning's problems with the use of the term "Bayesian"
> and equating it with "subjective". Personally I think this paper should
> avoid such specialist technical terms if possible, especially if there
> is disagreement about what they mean!

Yes: Bayesian methods provide a means of combining prior (expert) knowledge with data to quantify the posterior distribution. The prior knowledge may be based on the results of previous experiments and need not be subjective. Another point is that formal application of Bayesian methods usually leads to problems that are analytically intractable. The recent development of Markov chain Monte Carlo methods has largely overcome this.

> 8. I repeat my concern re too much spatial aggregation of results if it
> hides important regional differences, as these are very important for
> questions of intragenerational equity. I think the paper should
> specifically warn against this. Averaging is notorious as a way of
> hiding important differences.

I share this concern: the average of a large negative and a large positive number is close to zero.

Subject: IPCC Emissions Scenarios
Date: Fri, 18 Dec 1998 15:34:41 +0100

LS

As you may recall, the Intergovernmental Panel on Climate Change (IPCC) is in the process of preparing a Special Report on Emissions Scenarios (SRES).

Recently, it has been agreed that these scenarios are to play an important role in IPCC's Third Assessment Report. The Terms of Reference of this Special Report include a so-called Open Process to stimulate input from a community of experts much broader than the writing team. This Open Process has started in August 1998 and was planned last until the end of the year.

Because of the late date of this message we decided to extent this deadline

until January 10 now. A website (sres.ciesin.org) is managed by the Center

for International Earth Science Information Network (CIESIN) in the United

States in collaboration with the Energy Research Foundation (ECN) in the Netherlands, the Technical Support Unit (TSU) of Working Group III on Mitigation of IPCC in the Netherlands, and the International Institute of Applied Systems Analysis (IIASA) in Austria, the home institution of the co-ordinator of the SRES Report, dr. Nebojsa Nakicenovic. Three types of input are invited: (a) new scenarios (preferably from the peer-reviewed literature) that have not been taken into account by the writing team,

(b) new quantification of the proposed SRES scenarios based on storylines, and

(c) suggestions for improvements of the material developed until now.

Several of you have responded to an earlier request for input into this open process. Thank you for that input. Amongst other things on the basis of input received so far, recently the information on the website has been

improved considerably. The writing team of the report has now started to actually draft their report, but can still take into account reactions to this new information as published through the website, in principle until 31 December 1998. Herewith I would like to invite you to explore the site (again) and provide us with your comments.

PLEASE DO SO USING THE FACILITIES OF THE WEBSITE, DO NOT USE THE EMAIL ADDRESS OF THE SENDER OF THIS MESSAGE OR THE EMAIL GROUP LIST ABOVE!!!!

On behalf of Dr. Nakicenovic, thank you very much for your support to this important endeavour!

Dr. Rob Swart

Reply-to: "Stepan G. Shiyatov" <stepan@ipae.uran.ru>

Dear Keith,

Thank you for the money transfer via Fritz Schweingruber. I received 5000 USD. Is it necessary to give you a receipt for this sum of money? Money will be used for organization of field works in the Yamal Peninsula and Polar Urals next year. Of course, this sum is not enough. I hope we shall have an additional money from the INTAS project and the Russian Funds.

I received two copy of the INTAS contract from Fritz and one copy I sent to E. Vaganov. We would like to know your opinion concerning transfer money.

Also, I need to know exact time you and Fritz intend to visit Ekaterinburg next year. The new rules demand to make application to the Russian officials before 6 months of your arriving. Do you want or not to travel in the area of Southern Ural Mountains after meeting in Ekaterinburg? Fritz wants to travel over this area (the Taganai and Iremel Mountains).

Best wishes to you, your family and your colleagues.

Marry Christmas and Happy New Year!

Sincerely yours,

Dr. Stepan G. Shiyatov

1. ESF on Copyright Law

The European Science Foundation is warning that current plans for new EU copyright laws, if left unchanged, could harm the international competitiveness of European research. The Commission's draft Directive harmonising aspects of copyright will shortly be debated by the Council of Ministers. The ESF is calling for changes to be made to the wording of one of the Directive's key articles which deals with 'exceptions' to the proposed laws to ensure that it doesn't cause legal and financial headaches for Europe's researchers.

The Foundation supports the Commission's objectives of improving the protection of intellectual property as technological developments make it ever easier for pirates to duplicate and distribute copyright material. But it warns that this should not be at the expense of Europe's ability to carry out research. Reflecting widespread concern in its Member Organisations, the Foundation argues that the draft Article 5, which deals with 'exceptions' to the proposed laws, "could result in research being treated differently in different countries across Europe". As presently written, the Article sets out an exhaustive list of permissible exceptions to the directive, but it leaves to Member States the interpretation and implementation of these 'exceptions'. The effect of this could be that some researchers might find themselves in a worse position than at present regarding their access to and use of published material. Given the differences in national legislation between Member States, the ESF recognises it may be difficult to draft and agree prescriptive legislation for 'exceptions'.

The Foundation is recommending, therefore, that a clause be added to the Directive allowing for the inclusion of all current 'exceptions' set out in national legislation. Other suggested revisions include the need to ensure that 'scientific research' is interpreted in a broad sense, with research in the humanities and arts being explicitly included. In addition, the ESF suggests that the current reference to 'non-commercial' research could cause confusion, as it would be very difficult to differentiate between commercial and non-commercial research in most academic settings. To avoid this, it recommends the introduction of a 'public good' definition of research, which could form an 'exception' to the Directive. The Foundation's statement also points out that the Directive's current reference to the possibility of Member States exempting the use of work "provided that such use exclusively serves the purpose of illustration for teaching or scientific research" is ambiguous. It could be interpreted that there is such a thing as 'illustration for research' and that any 'exception' did not apply to research in general. A simple rewording of the sentence to read "sole purpose of scientific research or for illustration for teaching" would clarify the 'exception'.

The European Commission's draft "Directive on the Harmonisation of Certain Aspects of Copyright and Related Rights in the Information Society" is available on-line at <http://europa.eu.int/comm/dg15/en/index.htm>

FURTHER INFORMATION: Johanne Martinez, Information Officer, European Science Foundation, tel 0033 3 8876 7114, fax 0033 3 8837 0532, email: jmartinez@esf.org, URL: <http://www.esf.org>

2. GENERAL - Policy documents

Recent policy documents issued by the European institutions. Full titles and details appear on the UKRO web site under the subject listings:

- * Community action programme in the field of Civil Protection
- * Action programme for customs in the Community
- * Further actions in the fight against trafficking in women
- * Further actions in the fight against trafficking in women
- * Better lawmaking 1998: a shared responsibility Commission report to the European Council
- * Determination of the person liable for payment of value added tax
- * Legal aspects of electronic commerce in the internal market
- * General framework for Community activities in favour of consumers
- * Action programme for customs in the Community

3. DG V - Newsletter on Alzheimer's Disease

The first edition of the Alzheimer Europe quarterly newsletter has been

published by DG V (Public Health). The newsletter is intended to draw attention to the aims and activities of Alzheimer Europe, a grouping of national organisations dealing with Alzheimer's disease. The newsletter includes news of research, events and conferences relevant to the field. It will focus on important developments in the European institutions which affect people with dementia and is also intended to be a platform for the exchange of ideas between organisations and institutes active in the field of Alzheimer's disease. Each issue will include reports on EC-funded transnational projects, beginning in the first edition with London's Institute of Psychiatry EUROCARE project. The next edition of the newsletter will be published towards the end of March 1999.

FURTHER INFORMATION: Alzheimer Europe, tel 00352 297 970, fax 00352 297 972, email: info@alzheimer-europe.org, URL: <http://www.alzheimer-europe.org>

4. Microbiology - Industrial Platform

The Industrial Platform for Microbiology, a ginger group of EU-funded companies and researchers, has decided to change the focus of its activities. It will now aim to provide a forum for EU industrial microbiologists to discuss research and development strategies, scientific aspects of regulatory developments in applied life sciences, and professional issues such as education and training in the field. The Industrial Platform for Microbiology was originally established to organise information exchange between EU-funded companies interested in using the results of EU funded projects and academics working on microbiology research and development projects. Its members will meet again in Brussels in February 1999 to discuss a draft "code of conduct" for companies involved in bioprospecting activities.

FURTHER INFORMATION: Anne-Marie Prieels, Tech-Know Consultants, tel 0032 58 513 953, email: anne.marie.prieels@skynet.be, URL: <http://www.tech-know.be>

5. ENVIRONMENT - Policy documents

Recent policy documents issued by the European institutions. Full titles and details appear on the UKRO web site under the subject listings:

- * Present situation and prospects for radioactive waste management
- * Minimum criteria for environmental inspections in the Member States
- * Cooperation in the field of accidental marine pollution
- * Limitation of emissions of volatile organic compounds due to the use of organic solvents
- * Review clause Environmental and health standards four years after the accession of Austria, Finland and Sweden to the E. U.
- * Application of aerial-survey and remote-sensing techniques to the

agricultural statistics for 1999-2003

- * Financial instrument for the environment
- * Forestry strategy for the E. U.
- * Control of transboundary movements of hazardous wastes and their disposal
- * Voluntary participation by organisations in a Community eco-management and audit scheme
- * Remote sensing applied to agricultural statistics during the period 1994-1998

6. Synergy - International Cooperation in Energy

The Council has announced a Decision (1999/23/EC) adopting a multiannual programme to promote international cooperation in the energy sector (1998-2002). According to the Decision, within the European Union's Energy Framework Programme (see EN39:98, item 11), a specific programme for reinforcement of international cooperation in the energy field will be implemented from 1998 to 2002 ('Synergy programme').

The objectives of this programme are to provide assistance to third countries with the definition, formulation and implementation of energy policy, and to promote industrial cooperation between the Community and third countries in the energy sector. The main tasks of the Synergy programme are to help achieve the Community's energy objectives: competitiveness, security of supply, and protection of the environment.

The financial reference for the Synergy programme will be ECU 15 million. Of this, ECU 6m will be for the period 1998 to 1999. The finances for the period between 2000 and 2002 will be reviewed if the amount ECU 9m is not consistent with the financial perspective for that period.

Supported activities are:

- * Energy policy advice and training;
- * Energy analyses and forecasting;
- * Energy dialogue and exchanges of information on energy policy, notably by means of organisation of conferences and seminars;
- * Support to regional transboundary cooperation;
- * Improvement of the Framework for industrial cooperation on energy.

According to this Decision, **NO FUNDING MAY BE GRANTED TO RESEARCH, development, or demonstration projects.**

FURTHER INFORMATION: OJ L 7 of 13 January 1999, p.23.

7. Public-Sector Information

The European Commission has decided to publish a Green Paper on how the information gathered by government departments and other public bodies can be used to provide the greatest benefit for citizens and businesses in Europe. A lot of information gathered by public bodies for carrying out their duties could be used by the multimedia industry for developing new products and services. Citizens could make better use of their rights if, for example, information was readily available on the conditions for working, studying or living as a pensioner in other Member States. Many people would like to have full information on the tax regulations for cross-border purchases. The competitiveness of businesses could be increased if they had a quick and easy means of finding out what the regulations and procedures are for exporting to other countries. All this information exists, but the technical and legal procedures and terms under which the Member States make it available are uncoordinated and therefore not very transparent for citizens and business. The Green Paper calls for these matters to be discussed and asks questions about how the situation can be improved.

FURTHER INFORMATION: <http://ww.echo.lu/legal/en/access/access.html>

8. Results - Pilot Projects on Benchmarking

Results from four pilot projects on benchmarking framework conditions - in the fields of professional qualification, logistics, the impact of new information technologies (NITs) on company organisation, and the financing of innovation - are reported in the January issue of the newsletter of the European Association of Development Agencies (EURADA).

The lessons drawn included:

- * Companies located in peripheral regions suffer from the poor quality of infrastructures, expensive logistical services and weaknesses in the field of transnational cooperation;
- * The authorities should support the effective use of NIT and the enhancement of NIT-related structures;
- * SMEs lack NIT qualifications and skills;
- * Business Angels play a lesser role in innovation in Europe than in the US, probably due to tax- and revenue-related problems;
- * Even though it remains below the number of such companies operating in the US, the number of venture capital companies operating in Member States of the EU is rising (750 versus 1800);
- * Generally speaking and in comparison with the US and Israel, Europe suffers from a deficit in terms of the ability to evaluate technological risks and from a lack of initiatives to support faster interaction between universities and companies;
- * Education policies should be more practical and in-company training

should be fully integrated in the programmes of higher education institutions;

* Closer links should be promoted between industry and the educational system;

* The skills which new workers lack most upon entry to the labour market are (a) knowledge of English, (b) computer literacy, (c) knowledge about the industrial world, and (d) adaptability.

FURTHER INFORMATION: EURADA, Avenue des Arts 12/7, B-1210 Brussels, tel 0032 2 218 4313; fax 0032 2 218 4583, email: info@eurada.org, URL: <http://www.benchmarking-in-europe.com>

9. Communication on Industrial Policy

The Commission has adopted a communication launching an open debate with the EU's different political, economic and social players on the orientation of a new industrial policy with a view to addressing the challenges of globalisation and accelerated technological changes. The communication diagnoses European industry's weaknesses and proposes a series of measures to promote industrial competitiveness.

The communication diagnoses the weaknesses of European industry:

- * Europe does not have a strong presence in the services sector;
- * European enterprises resort to insufficient externalisation;
- * Specialisation remains underdeveloped in sectors with high growth, highly differentiated products and requiring a strong marketing strategy;
- * The European audiovisual sector is in an unfavourable competitive position;
- * European enterprises form relatively few alliances in advanced technology areas;
- * The amounts invested by risk capital funds are insufficiently oriented towards new and high- technology industries;
- * European enterprises can access financial markets only with difficulty;
- * The level of R&D spending in terms of EU GDP is still below that of its principal global economic partners;
- * The exploitation of research results is not efficient enough;
- * The EU suffers from high costs and the complexity of procedures for achieving intellectual property protection in Europe;
- * European enterprises put very few joint research projects in place.

To counteract this situation and stimulate European competitiveness, the communication emphasises the following proposals, among others:

- * Reinforce intangible investment, by adapting the systems of accrediting competencies and by improving the level of and return from research resources, especially through a better system of intellectual property protection;

- * Develop human resources by acting on the educational system, by encouraging the spirit of enterprise and various forms of social innovation and social cohesion;
- * Promote the access of European enterprises to the world market, by accelerating the exploitation of the competitive advantages of the Single Market;
- * Promote fair rules of the game at a world level in view of the new round of WTO negotiations (that is by developing an observation system for public support to research in industrialised countries);
- * Develop the dialogue between industry and public authorities and forms of self-regulation (protection of consumers and users);
- * Improve financing by eliminating institutional and regulatory barriers to the development of venture capital and improving the tax regime applied to venture capital;
- * Adaptation of the rules to the context of the information society and electronic commerce (agreements such as the "International Charter").

FURTHER INFORMATION: Press release IP/99/33.

10. Leonardo Database on Cordis

DG XXII and Cordis have approved plans to include the products database of the Leonardo da Vinci Programme on the Cordis service. The publication of the Leonardo Da Vinci products database on Cordis should allow its continual update. This is hoped to improve interaction between the owners of products and their users. The schedule for the launch of this database on Cordis has yet to be confirmed.

FURTHER INFORMATION: DG XXII, fax 0032 2 295 5699, URL:
<http://europa.eu.int/en/comm/dg22/leonardo.html>

11. Mid-term Review for Structural Funds

The European Commission approved a report on the mid-term review for the poorest (Objective 1) and sparsely populated regions (Objective 6) in the European Union (EU) for the present programming period (1994 1999). It gives an overview of the mid-term evaluations carried out for the Structural Funds programmes during the current programming period. The report shows important achievements, e.g. when it comes to reducing disparities in basic infrastructure, energy diversification or environmental improvements.

Subject: Re[2]: IPCC Chapter 13 - invitation to contribute
Date: Tue, 2 Feb 1999 20:21:47 +0100
Reply-to: Wolfgang Cramer <Wolfgang.Cramer@pik-potsdam.de>

Dear Mike,

thanks for your message. I am sure we can work with these files as soon as we know how the grid is organized. Is it line by line from the North to the South, starting at the dateline? Or something different?

Yes indeed, it would be the best to work with **your** 61-90 baseline for this. Does the baseline also contain cloudiness? If not, then I intend to generate that from our own files, and we will make the assumption that, on the level of monthly means, this does not change as much as to significantly affect the sensitivity of vegetation to the other forcings.

As for a minor point, please remember to use my pik-address whenever possible. The other two (csi and t-online) are both used for sending mail while I am on the road (csi) or at home (t-online), and particularly t-online has the drawback that I can ONLY access it from home (presently) and not from the lab. Unfortunately, I cannot convince my mail sending software to always pretend the mail comes from PIK...

Yes, I will come to the ACACIA meeting, at least until the second day in the afternoon - after that I have to juggle two other meetings in Holland and Germany. With some luck, I should be able to present some results there.

Best wishes!

Wolfgang

PS: I saw your correspondence with Kinne and am interested to follow up - but not today.

Hi Frank and friends - I'm happy to see the budget looking sound and feel Franks suggestions are good ones in terms of money to spend this year. Building on the Swiss paleoclimate course is a good idea, and, of course, we should decide on future REDIE investments at future SSC's. My gut feeling is that REDIE will have to continue to be a lower priority in the future, BUT that we should stay committed to getting scientists (including youngsters) from developing countries to our science mtgs - makes more sense than training probably, given tight budgets. Thanks,Peck

>Dear colleagues,

>

>I now share with you some ideas about our financial situation in PAGES. I

>think the information should be treated confidentially at this stage and

>certainly with some discretion.

>

>During the course of last year, it was very difficult to keep track of our

>financial position from month to month, partly because it took our

>financial contacts in the University of Bern an inordinately long time to

>sort out the financial implications of the OSM, partly because, in the

>course of doing this, they made some understandable but very significant

>and confusing errors. Niklaus has now managed to sort these out and we also

>have our confirmed budget for 1999 - which means that we can begin to do

>some real planning.

>

>The first significant point is that we are carrying over into 1999 a

>surplus some US\$15k greater than we began with in 1998. In fact we have

>been building up our 'carry-over' steadily since the beginning of 1996 and

>it is now around \$67k - between 13% and 14% of our annual budget and a much

>higher proportion of that part of our budget that is uncommitted each year.

>Whilst I believe it would be unwise to eliminate it entirely, I do think we

>should aim to reduce it significantly provided there is a good rationale

>for the means we choose.

>

>I have attached a summary of how I see things for 1999. You will see that

>even if we spend all the funds committed to workshops at our Pallanza

>meeting, we still have a very healthy surplus. On past experience, I do not

>think this sum will be exceeded during 1999 - even if we have one or two

>more urgent requests, they are more than likely to be offset by delayed

>workshops, so I think this is actually likely to be an over-estimate.
>Moreover, I have assumed that ALL the money allocated by IGBP for Synthesis
>will be spent in 1999. We are under some pressure to do this, but the pace
>of the exercise makes me suspect that we may have difficulty.

>
>At the end of the Table, I list 3 additional commitments I would like to
>propose for prioritizing and I discuss each briefly below:

>
>1. REDIE (which you may remember stands for Regional Educational and
>Infrastructure Efforts (about which we have, so far, said very little and
>done even less).

>
> In this area, one of the ideas gently simmering on the back burner has
>been the notion of winning support from START to run something like a
>Summer School for selected young scientists from developing countries. This
>emerged from an informal discussion between ourselves in the Office, Bruno
>and Roland Fuchs, the Director of START, when he was over here on a visit.
>At the time, he seemed quite keen on the idea, but has since been silent.
>No matter, I still feel it is an idea worth working towards at least up to
>the pre-commitment stage and I have been exploring informally the
>possibility of basing such a course in London.

>
>This coming summer, I think we may have a chance to do a kind of partial
>trial run. Thomas Stocker and Andy Lotter (a first class paleolimnologist
>here in Bern) plan to run a Summer School nearby this year. Thomas
>approached me some time ago to see if PAGES could support participation by
>any overseas students and my reply was a very cautious one to the effect
>that we would normally expect to be approached and have an input at the
>planning stage and that we would only really consider such a possibility in
>the context of training for scientists from developing countries. Having
>discussed the whole thing more fully with him, I begin to wonder whether
>it may offer quite an interesting possibility. My plan would be to seek
>nomination of/applications from say 3 to 5 young scientists from different
>parts of the developing/former eastern bloc world (representing each of the
>PEP Transects) and bring them to Bern both for the course and for a short
>period linked into the PAGES Office. The ideas behind the latter part of
>the suggestion would be to
> - support their participation if need be,
> - give them some sense of PAGES and its role in international global
>change science/IGBP etc and
> - solicit feedback and advice about what the shape of an ideal course for
>developing country scientists interested in PAGES activities might be.

>
>I believe that even if we did not have something like REDIE in our
>Implementation Plan it should be an important commitment; since we do, it

>is an absolute obligation which we ignore at the risk of serious
>allegations of bad faith.

>

>2. I feel there will be a need to follow up my PEP II visit to Australia
>with something positive there. John Dodson is responding well to
>suggestions about more co-ordination and bringing in more colleagues to
>share the responsibility, but I think that if whatever we agree in Perth is
>actually to work, there will be a need to fund a WORKshop (as distinct from
>a mini-symposium) of thematic and/or regional co-ordinators to get their
>act together. We should offer money for this.

>

>3. The difference it has made having Cathy Stickley (based at UCL) working
>for PEP III is fantastic, but we risk losing her input unless something can
>be done. I'm negotiating with ESF, but it will be over a year before their
>finely grinding mills deliver anything. Rick and Francoise are also going
>to apply to EC for Framework 5 funding, but that will be no quicker. I am
>seriously considering asking Zimmie to help bridge the gap since he did not
>quite close the door when I last talked this through with him, but I feel
>that if I do this, PAGES might need to put up a bit more colateral, the
>more so since we are in credit.

>

>Both 2 and 3 reflect my view that the PEP's remain an absolutely vital part
>of the PAGES structure and need to be supported if that is the only way
>they can achieve their objectives.

>

>All three of the above suggestions require some endorsement in principle
>before I take them any further. If we were to spend all the funds envisaged
>before the end of 1999, our budget credit would be very much reduced -
>probably by too much, but I believe the PEP funding would probably be paced
>over a longer period and that the other items in our budget are more likely
>to be marginally under- than over-spent, so I do not feel we are proposing
>any unreasonable risk.

Subject: Tuesday Meeting

Date: Wed, 17 Feb 1999 23:01:45 +0000

Dear all,

thank you for the meeting on tuesday. I think it went well. Here as promised and slightly late is a summary of what we discussed. Myles can you forward the message to Michael. Can you let me know if you are all happy with this and once I have made any corrections you want I'd like to send it to John, Geoff and Tim Barnett -- anyone else you think should get it?

Proxy Climate forcing.

Solar -- Beer has a Be based proxy reconstruction of Solar ACTIVITY which can be converted to irradiance changes. [Is it different from LBB or H&S ?] Has the LBB dataset been updated? Has Svensmark got a better handle on his proposed physical mechanisms to amplify solar irradiance changes? [Someone to check at RMS meeting which I won't be able to attend] Want forcing back to 1600?? though HC would find it hard to justify doing runs that early -- me to see if John/Geoff think useful or not.

Me to check with William the source of the rumour about problems with the H&S dataset.

Volcanoes. Volcanoes are an important climate forcings [Issue for IPCC??] Do volcanic eruptions cluster? Myles to "persuade" a student to look at Phil/Keith's dataset and see if there is evidence for this? Are there other indices of volcanic activity? Is climate response to volcanoes sensitive to mean state?? i.e. in cooler climate get bigger response. [Gareth could see from our model if Krakota response significantly different from Pinatubo]

Proxy Climate data + comparison with obs and models.

Keith/Phil have 400 sites of high quality tree ring density data which there are willing to let HC (Mat) use to do a crude model/data comparison. Mat and Tim to liase on what they are doing. Note that funny things are happening in the density data post 1950. Also available may be some borehole data [Phil to talk to Pollock/Wang about possibility] which could use to compare with model -- should consider using lower soil temperature rather than 1. m temp. There are a few sites with data from 0A to 2000 as well as many sites with data for 1700 to 2000 -- should consider both. There may be some other tree ring data which tells us something about SW USA precip and thus ENSO.

Tim wants to compare patterns of temperature var from the proxy data and compare that with the models i.e compare "observed" and modelled covariance structure rather than just the variability. Also Tim wants to try and unpick Mann's stuff.... HC to provide solar forced run from 1700 -- Me to check if it goes from 1700!

Our approach will be to compare model data "directly" with Proxy data rather than do Interpolation a la GISST or Mann et al.

EU proposal

Not clear if in this years framework 5 call there will be room for Detection/Attribution proposals (which is how we'd like to frame a model/proxy comparison). Other issue is that QUARCC 2 and model/proxy comparison could involve similar institutions which could cause problems. Phil to check if room this year for proposal. Keith pointed out that we can't just recycle the NERC thematic proposal (PRESIENT). There is good news on that front which suggests the proposal will go through with an 8 million pound budget!!!

Ad Hoc detn group.

Not much said on that (or at least I didn't note it) Phil -- you have some advice for me on that?

CLIVAR/PAGES

In the next 1-2 years there may be new reasonable quality ice core and sedimentation data available. Data availability from the proxy and modelling groups is an issue (another reason for an EU proposal!).

Phil pointed out that there is a lot of instrumental data (in "funny" units) which could be digitised in Europe.

Keith is planning on writing a "call to arms" paleo data paper.

I think I need to come up with a list of actions.... Anyone want to volunteer.....

Simon

Subject: Some things of possible CLIVAR interest
Date: Thu Feb 25 17:08:21 1999
Cc: t.osborn@uea,p.jones@uea

Dear Fred,

The following legends refer to the appropriately titled post-script files that will be sent to you separately by my colleague Tim Osborn.

Please note that these results are products of the European Community funded project ADVANCE-10K (Analysis of Dendrochronological Variability and Associated Natural Climates in Eurasia - the last 10,000 years). Environment and Climate Programme Contract ENV4-CT95-0127. See also <http://www.cru.ac.uk/cru/research/>

As I said on the 'phone , due acknowledgement of the above is important to us!

Figure 1

Annually averaged tree-ring density data from 400 high-latitude or high-elevation sites around the Northern Hemisphere. This series represents interannual and multidecadal summer temperature variability from A.D.1400 onwards. This series shows circum-hemispheric summer temperature variability on interannual and multi-decadal timescales and demonstrates the relative cooling effect of known, and some probably as yet unknown, large explosive volcanic eruptions.

Figure 2

Normalized tree-ring -density anomalies around the Northern hemisphere showing patterns of likely summer temperature changes year by year through the relatively cool decade of the 1810s, in part caused by major volcanic eruptions in 1809 and 1815.

Figure 3

Decadally-smoothed timeseries of standardized radial tree growth at three high northern latitude regions during the last 2000 years : Tornetrask, N.Sweden (20E); Yamal(70E) and Taimyr(102E), Russia. Positive and negative values of these data represent relatively warm and cool summers, associated at each location with the strength and position of large-scale atmospheric circulation features.

I have asked Phil Jones here to send you a post script file and reference for the mean 1000-year Northern Hemisphere curve. His email address is shown above.

You may be also interested in some reconstructions of the NAO made by various people. If so ask Tim about these.

best wishes
Keith

Subject: URGENT - IPCC DDC consultation
Date: Thu, 01 Apr 1999 12:46:01 +0100

Dear TGCIA'ers,

I have two questions to raise with you regarding the IPCC Data
Distribution
Centre. The first one concerns advice regarding a GCM submission to the
DDC and the second concerns mirror web sites for the DDC.

1. GCM submission.

The LMD (through Herve Le Treut) has requested the runs from LMD coupled
GCM be lodged with the DDC. His original request (July 1998) is appended
below as text ATTACHMENT 1. We originally rejected the submission on the
grounds that the runs were not historically forced, i.e., they were
cold-start experiments with 1% p.a. forcing being introduced from
'current'
baseline and different to all other DDC runs.

However, LMD have re-submitted their request for reasons outlined in
ATTACHMENT 2 which is an email from my DDC Co-Manager Michael
Lautenschlager (dated 12 February 1999). In this ATTACHMENT Michael
makes
a proposal to include the LMD model runs, but as 'related modelling
results' rather than as 'full status' DDC results.

We need to take TGCIA soundings on this. Strictly, the LMD runs do *not*
qualify according to the criteria the TGCIA established back in May 1997.
The question is how flexible are we prepared to be and whether including
model runs with a different experimental design may either a) confuse
impacts users and/or b) invalidate inter-model comparisons. Bear in mind
also that if/when new GCM results forced by SRES forcings are generated
this summer and beyond, we will need to consult again about how the DDC
handles/presents these new SRES runs. At present the DDC does not have a
mandate for these either.

Please would you submit your opinions to me by Monday 12 April. I will
then compile the views expressed and make a recommendation.

2. DDC mirror web sites.

With the DDC web site now fully operational (and the CD-ROM about to be released) we need to consider our idea for mirror sites around the world. Users are picking up data and information from both the Yellow Pages (full GCM archive site) and Green Pages (synthesised GCM results, observed data, and other scenario data and visualisation), but for some users/regions/operations access is very slow.

Proposed mirror sites might include: CSIRO (Victoria), IIT (Delhi), NCAR (USA) and Cape Town (S.Africa). Maybe a Japanese site also.

The mirror sites could consist only of the Green Pages (about 0.5GB requirement) or both Green and Yellow Pages (several GB requirement, but I have not checked exactly how much with DKRZ). I know that we can arrange for the mirror sites to automatically refresh every 24 hours therefore reflecting perfectly any developments on the host mother-site (i.e., the mirror sites must be perfect mirrors).

Could I also ask for your views on the desirability of these options, whether Green only or Green plus Yellow, how many mirrors and where they should be? Please let me have your views on this also by Monday 12 April.

In considering both these questions it is perhaps worth thinking about the longer-term future of the DDC beyond TAR and into 4th IPCC Assessment. Although TG CIA and the DDC has now only a mandate through the lifetime of TAR, for us to really learn from our experiences and to achieve full benefits for IPCC, then we need to be thinking ahead beyond year 2000.

Mike Hulme

Date: 9/7/98 9:08 pm

Dear Maria,

At the IPCC meeting a week ago, I spoke with M. Hulme concerning the possibility of having our simulations being integrated in the IPCC

data base (DDA?)

I think that our simulations meet a number of the criteria:

- the control simulation is 200 years long
- the model has participated to CIMP1 and CMIP2
- it is described in details (description posted on the WEb in the Euroclivar Web site: <http://www.knmi.nl/euroclivar>)

Our main problem concerns the definition of the experiments. We have used a model without flux correction and have decided to start from observed Levitus data. The coupled model has some drift but it stabilizes rather quickly and the thermohaline circulation is quite stable

Accordingly our initial CO2 value corresponds to a recent past: 320 ppm. >From that value we have increased directly the CO2 concentration of 1 percent per year. We have therefore not allowed for an 'historic' increase of the CO2 before the actual 1percent increase, which is due to a lack of understanding of the IPCC rules.

My feeling is that scientifically this is not too important (we have no 'cold start' symptom when we look at the difference between the perturbed and controled run). I have realized that in the context of the IPCC, however, people may think otherwise.

My question is two-fold:

- Can our experiment nevertheless be integrated in the IPCC data base. This is important to us: if it cannot we will not realize the sulfate experiment we had planned to do, and wait for the future scenarios to be decided.
- I hope that I will be more easily aware of the IPCC initiatives in the future. But is there any procedure through which we can make sure in advance that a given experiment we decide to carry out does get approved by the IPCC?

Sincerely yours

Herve

ATTACHMENT 2

Hamburg, den 12. February 1999 (15:00)

Dear Maria and Mike,

last week I have a discussion with Herve LeTreur from LMD in Paris about the DDC rejection of the French contribution to the climate scenario calculations. He informed that the climate modellers are running into political difficulties because no French data are contained in the DDC.

We have rejected the data last year because they design of his experiments are not directly comparable to the DDC requirements. A recalculation is not possible within short term.

In order to prevent the French colleagues from difficulties I suggest to install an additional section in our DDC page which may be entitled 'DDC related modelling results'. In this section Herve`s data as well as data from other groups can be disseminated. The processing priority is certainly lower than for the direct DDC data.

Do you agree with my suggestion?

Best regards, Michael

Mike

I am off to Finland for a week but I am sending you (via Tim) a copy of a draft perspectives piece for Science on your recent 1000-year reconstruction paper. They want to run it in early May I think and I have been told I will see their edited draft on my return. The idea was to make a wider comment that just report on your latest curve so I decided to mention uncertainties in tree-ring data while pushing the need for more work on high-resolution proxies and especially interpretive work in the very recent context of high temperatures and other possible anthropogenic environmental disturbance. The trouble is that they would only give us 1000 words and one Figure. Anyway this Figure now contains a selection of various large-scale temperature average series - all recalibrated against northern warm season (April-Sept) average land data north of 20 degrees north. This is just to provide a convenient common scale - all the original season /area references are given. You will see that this brings Phil's curve nicely back in line and the correct (low frequency) density curve now fits better also. I have taken the opportunity to put our new longish (2000-year) tree-ring width curve in representing the north of Europe/Siberia. This is the average of Tornetrask (Sweden) and Yamal and Taimyr (Siberia) - all processed to retain low-frequency variance. These curves and a similar average incorporating all the Northern tree-ring data (not including the large density set) are in my paper for the Pages open science meeting publication. Tim and I will produce a short paper describing the new low-frequency density curve, probably for Geophysical Research Letters. For the meantime I hope you think the perspectives piece is O.K. Let me know if you have any problems with it - but remember that they are going to hack it about anyway. By the way, how did you compare the high-elevation (PC1) timeseries with Jacoby and D'Arrigo's northern treeline data in your paper when the latter only go back to 1671? Did you use their reworked Gidding's dataset for Alaska?

Thanks for the message on the IPCC stuff. I am happy to write any additional bits or make suggestions. Sorry I did not get back to you last time but I was confused about the timetable. Thanks for putting my name on the list. I will make comments again as soon as I see the next draft. Cheers

Keith

Dear Keith

(Tim, please get this to Keith by FAX or other means, if he is unlikely to have received this at his own email while traveling).

It's a good piece overall. As you might suspect, I do have several comments. Ray and Malcolm may send along a few of their own. Malcolm in particular may want to comment on some of your points regarding dendroclimatic series and our ITRDB PC#1 series which figures so prominently in our millennial reconstruction.

1) page 2, top paragraph:

It's is very misleading to make it sound as if we are strictly reconstructing northern hemisphere mean temperature, and then say "4 of the records are actually from the southern hemisphere locations". This is misleading for a number of reasons. First of all, if one is going after true northern hemisphere areally-weighted mean temperature 0-90 degrees (as we are), then the southern hemisphere tropics are actually more relevant than the high-latitudes of the Northern Hemisphere. Careful diagnostics of surface temperature covariances by Alexey Kaplan, Mark Cane and others have shown this clearly to be true. BUt more than that, we are reconstructing the full 20th century surface temperature domain shown in Figure 1 of our '98 Nature paper. This is a GLOBAL domain, albeit sparse outside the southern hemisphere tropics/subtropics, particularly the southern oceans, for obvious regions. THE proxy network roughly overlaps the spatial domain of surface temperature we are reconstructing (ie, compare Nature '98 figure 1a and figure 1b). We choose to diagnose from this spatial domain the northern hemisphere mean only because that is the hemisphere for which we can meaningfully talk about a true hemispheric mean. But both the predictor and predictand have a global distribution. Without going on and on, I think its clear why your comments here are a bit unfair in how they represent why we use southern hemisphere data. This is probably the most important point that needs to be revised here.

2) page 2, 2nd paragraph

A minor point, but an important one: It is incorrect to say the our uncertainties are based only on "a consideration ...goodness of fit...over the calibration period"! This is not correct. A key point is that the verification period (1854-1901) diagnostics (though based on a somewhat sparser distribution of gridpoint data from which NH mean temp can be estimated) give very nearly identical diagnostics in terms of unresolved reconstructed NH mean temp variance. So our uncertainties are based both on 20th century calibration and independent confirmation from 19th century data. PLEASE MAKE SURE this is clear.

On the bigger point being made here, I agree w/ you in principle, and this is a point that Phil has raised too: what we *DONT* take into account (though I challenge anyone to really ever be able to take this into account!) is the unknown potential bias due to degradation from diminishing quality of the underlying proxy data back in time. However, on some of the specific points in that regard, it is very likely not a significant concern in our reconstructions. We closely examined the spectra of the underlying proxy data to insure that those upon which our reconstruction ultimately relies have the amount of millennial scale trend/variability that would be expected for a climatic series for at least the null hypothesis of red noise. Malcolm independently examined the tree ring chronologies underlying our ITRDB PC #1 to verify that the standardization was appropriately conservative for a millennial-scale reconstruction. Furthermore, Malcolm verified that the ITRDB PC #1 is made up of heavily replicated chronologies as far back as we use them. So neither of the points you raise appear to be all that relevant to our reconstruction.

With regard to this point, I have some issues with your Figure that accompanies the piece. It is quite ironic given your comments about the potential impacts of standardization on the long-timescale variations. For our millennial reconstruction we have verified as carefully as has ever been verified, that the millennial scale trend is likely to be meaningful. I don't think you have done so for the 2000 year-long trend in the series you show, and if you have not verified that it is likely to have retained 2000 year long trends, it is VERY misleading to show this series along with the others. I don't believe that it is likely to accurately represent the 2000 year long trend in Northern Hemisphere mean temperature, as you imply by showing it here. I think this series needs to be removed from the plot. I have a related comment

below (point #5).

3) page 3, 1st paragraph:

Remove "this is a moot point" and replace with more appropriate language. It is not "a moot point" because the problem you point out has largely been shown to apply to tree ring density data (which you have largely been using), and much less so tree ring width data (which we are using). Furthermore, the comparison only goes through 1980 at which point there is little evidence that there is a significant decline in tree ring width response, although more evidence that there is already a problem at that point with density data. Your criticism is not quite fair here, and the statements should be revised to reflect more accurately on what we have done.

4) page 3, 2nd paragraph:

When you talk about proxy-based ENSO reconstructions, you should mention our NINO3 reconstruction! This is complementary to Stahle's SOI reconstruction in a number of ways. The appropriate references here are both our Nature '98 papers, and the chapter in Henry Diaz's latest book (in the press):

Mann, M.E., Bradley, R.S., and Hughes, M.K.,
Long-term variability in the El Nino
Southern Oscillation and associated teleconnections, Diaz, H.F. & Markgraf, V.,
(eds) El Nino and the Southern Oscillation: Multiscale Variability and
its Impacts on
Natural Ecosystems and Society, Cambridge University Press, 321-372, Cambridge,
UK, in press, 1999.

if you care to, you can download the galley version here:

<ftp://eclogite.geo.umass.edu/pub/mann/ONLINE-PREPRINTS/ENSO-recon/>

in either pdf format (chapter-diaz.pdf) or postscript (chapter-diaz.ps)

5) accompanying figure (see also my point #3):

There are problems with the 2000 year series in terms of your definition of the baseline for comparing with the other series, and this differs quite a bit from what we are likely to be showing in IPCC. It appears that both the density NH reconstruction and your 2000 year long

series fall at least 0.1C below the other series during the 20th century, and are probably running at least that much too cold the whole way through.

Also, correct "global temperature and non-temperature proxies" in your description of our series to "global climate proxies" which is a more honest way of describing them given our methodological approach, and make sure it is clear to the readers which series are extratropical and warm season, and which are full northern hemisphere/annual mean estimates (ours). Such discussion will, again, figure prominently in IPCC, and it would be a shame for Science to be publishing something that is misleading in that respect. In part, it was this issue that forced the publication of a followup to Phil's perspective by me, Ray, Malcolm, and Phil a year ago, and it would be nice to avoid that scenario this time around...

Thanks for your consideration of the above comments. I believe your piece will make an excellent "Perspectives" article for Science, once these comments are appropriately taken into account. I'll leave it to the Science editor in charge to determine if that is the case.

best regards,

mike.

Subject: GROVE REVIEW
Date: Tue, 13 Apr 1999 16:33:08 -0400

Keith,

The attachment is in WORD and better formatted.

Brian

Dear Keith,

Enclosed please find my comments on Jean Grove's paper. It gives the impression of a cut and paste job written in haste with several minor annoying errors. It lacks the synthesis I would have expected and reads like a catalogue. The paper is also not as comprehensive as would appear from the title. Six months ago I reviewed a paper by her (for Astrid) on "The Initiation of the Little Ice Age in regions round the North Atlantic". The paper she submitted to you is clearly complementary and reviews " the rest of the world" for comparison with the classic areas discussed in the earlier paper. Yet the earlier paper is only alluded to once (rather coyly) and does not appear in the references. This surely has to be significantly recognised in the title and body of this paper, because as it stands, the review of this earlier (best dated) material is far from adequate.

I cannot speak for most of these data directly but the North American material I am familiar with is not particularly up to date (though in fairness most of Greg Wiles's stuff is still in press). I have sent her under separate cover copies of my Little Ice Age in the Rockies paper (about 6 months ago) and more recently the Luckman and Villalba review paper on glacier fluctuations of the last Millennium along the PEP-1 transect. (copies are on their way to you too).

I think her mixing the discussion of ice core records and glacier histories significantly muddies the waters on whether the term LIA should be used to refer to a glacier or a climate event. I feel this should be addressed and the paper needs a more effective conclusion. She must also decide whether she wants diagrams or tables.

I don't know how she will take these criticisms but, as she is just finishing revising the book, I would have thought she could have presented

a better synthesis. I leave it to your judgement as to how to deal with these comments. The paper could be much better but that depends on how much she is willing to reorganise and to some extent rethink what she has written.

I am sending you this e-mail. Do you want me to return the manuscript to you? If you wish I can also e-mail WORD copies of the two papers to you (and her) if you wish a rapid turnaround. But you will only get the diagrams by mail. If I don't hear from you tomorrow I'll just put everything in the mail.

Cheers

Brian

Review of "The Initiation of the Little Ice Age" by Jean Grove

This paper is a useful summary but needs significant fine-tuning and possibly retitling before it should be accepted. The title promises a comprehensive review that the text does not deliver. When I first read this paper I kept asking myself- where is the discussion of all the well-dated early LIA material from Switzerland, Canada and Alaska? Then I remembered the paper by the author that I reviewed 6 months ago entitled "The Initiation of the Little Ice Age in Regions round the North Atlantic". The present paper is not a global review of evidence but a companion paper that compares the "Rest of the World" with the "European/North Atlantic record" discussed in that earlier paper. The crux of the problem is the first sentence after the title "Little Ice Age Initiation ..." at the top of page 3. I initially read this to mean that Holzhauser had submitted a paper on the European record to Climatic Change. Careful re-reading suggests that the author is actually referring to her own review paper. This misunderstanding could be avoided by explicitly acknowledging, in the

introduction to the present paper, that the evidence for the circum North Atlantic Region has previously been reviewed by Grove (in press), giving the full citation in the references, and that the section entitled "LIA initiation in regions around the North Atlantic" is a brief summary of that review.

There are a number of general points that need to be made before discussing specifics.

1. This discussion begs the question of how one would recognise the beginning of the LIA (A question I raised in my earlier review) Why, for example is the line drawn between the 8-9th century medieval glacier advances and the 12-13th century ones? Possibly this is related to the author's definition of the so-called Medieval Warm Period which has recently been extensively discussed (Hughes and Diaz 1994). It might be useful to insert a brief discussion of the rationale for this boundary and a definition and defence of the use of the term Medieval Warm Period.in either the introduction or the final discussion section.

2. I also feel that there is a logical inconsistency in the way the author uses the ice core evidence in this paper. In her abstract Dr Grove indicates that "the term LIA refers to the behaviour of glaciers, not directly to the climatic circumstances causing them to expand " (abstract lines 3-4). I agree strongly agree with this usage to differentiate between a glacier event and a climatic event. However, the discussion of the definition of the LIA from the ice core work is based on either periods of greater annual snow accumulation or inferred paleotemperatures from isotopic records. i.e. these definitions are based on climatic events not glacial events. The author should perhaps address this dichotomy and discuss it more fully. If one wishes to argue for retaining the term LIA for the glacial event, it is inconsistent to identify it in ice core records based on temperature (or snowfall) records.

3. The author appears to have an implicit faith in the veracity of ^{14}C dates which I do not share and a disdain for minimum age dating based on lichenometry or dendrochronology. There is a strong emphasis on calendar dated ^{14}C ages throughout this paper and age determinations by other techniques are often significantly downplayed. The paper never specifically addresses the relative errors involved in age determinations by these various techniques. Lichenometry and minimum age tree-ring dating of moraines are disparaged yet, in this timeframe the error terms are almost certainly less than ^{14}C dates from equivalent situations (i.e. dates above glacier deposits or on moraine surfaces). The comments made in this paper

about lichenometric dating and dendrochronological dating of moraines (from minimum tree ages) only stress the likelihood of large errors through the use of these dating techniques. These comments may be appropriate for some moraines that date from the 12-13th centuries but they should not be unqualified, universal statements cannot remain couched in those terms. In most situations lichen and tree-ring minimum ages for moraines of the last 500 years or so are considerably more accurate than 14C ages would be.

4. In my review of her earlier paper I commented that I did not consider that sites in the Canadian Rockies could be described as "around the North Atlantic". In this paper, it makes no geographical sense to review the results from the Rockies separately from adjacent areas in British Columbia and Alaska which they closely resemble (see Luckman and Villalba, in press). I have no objection to the comment that the Rockies material was discussed in a previous paper (and will therefore not be repeated in detail) but surely in the context of this paper these results should be presented in the discussion of evidence from Western North America. Having recently reviewed the literature for North America I also note there are omissions of significant recent material that is recently published or in press (see Luckman and Villalba attached).

5. The Tables and diagrams appear identical except for Table 10. Tables 1-9 should be deleted?

More detailed and specific comments follow.

Page Para Line

1 3 4 why is lichenometry excluded?

1 4 1 Reference to Grove in press??

1 4 3. In this paper evidence from.....???

2 2 1-2 Is dating within the last millennium considered to be the critical defining factor in identifying a glacier advance as belonging to the LIA? See comment about the inception of the LIA, above.

2 3 1 delete orphan period before text

3 2 3 Holzhauser 1998 not in the references.

- 3 2 5 change phrase within brackets to (Grove, in press) and insert in references.
- 3 3 1 ... Rockies dating derived from ring width and.....(revise)
- 3 3 6 Also Stutfield after 1272 (Luckman , in press)
- 3 3 11 Luckman 1995, 1996a and b??? (there is no 1995 a and b)
- 3 3 14 Luckman 1991 not in references. Could be Luckman 1993? Luckman et al. 1997 (never referenced) or Luckman 1996
- 3 4 3-4 Given the dispute about the universality of the Medieval Warm Period (see Diaz and Hughes 1994) perhaps it would be better to indicate the dating here e.g. 10-13th centuries?
- 4 2 1-5 based on what evidence? Lichens, historical data , 14C?
- 4 4 What are these moraine dates based on?
- 5 2 1 delete comma
- 5 2 3 1991a or b?
- 4 1 8-9 snow cover extended? = period of snow cover lengthened between these dates?
- 5 3 end of several lines truncated in xerox copy sent to me
- 6 1 as above
- 5 3 3 not in references, Haeberli ?? Kuhn references also missing.
- 6 1 19 reference for Swiss example?
- 6 1 end negative summer temperature anomalies or negative annual anomalies?
- 7 1 2 said claimed ? = said or claimed?
- 7 1 5-8 admitted by who relative to what? This somewhat disparaging comment seems dismissive. Perhaps lichenometry is the only available technique. Is the author aware whether or not these glaciers ever extended into forested areas. Is there any wood associated with these moraines? Does the evidence

presented by these authors and their lichenometric dates indicate the presence of early LIA moraines?

7 2 7 delete end bracket

7 2 last What is being implied here? Were the samples dated of the same species, were the records long enough to crossdate?

8 Table 1 etc Are these Tables or Figures? The Tables within the text seem almost identical to the diagrams appended at the end.

9 2 1 and Footnote 5; Rothlisberger 1986 not in refs. Rothlisberger and Geyl??

9 3 2 Figure 2 and Table 2 seem identical which will be used?
References should be R and G 1986 not Rothlisberger 1986?

10 1 6 is thought?

10 1 9 geographically close or close in age?

10 1 last sentence surely should come after the next section?

11 1 last The glaciers or monsoon cover 46,000 square kilometers?

12 2 13 Why must it have preceded the LIA? based on a 14C age?

13 Table/Figure 3 explain XXXs

13 1 8 "The Dunde record shows the Little Ice Age clearly" This section needs to differentiate clearly between the glacier fluctuation record, the snow accumulation record and the isotopic temperature signal. If the term LIA is being used to define/describe glacier events then it cannot also be used- without qualification- to describe climatic events. The author is describing climate signals here not glacier advances. This section and the discussion on page 14 needs more clarification and discussion.

14 1 5 after 1264 based on what evidence?

15-16 Apart from a conference abstract listed in the references but not cited, there are no references to the spectacular work of Wiles in tree-ring dating of overridden forests in this area. In addition, the discussion of the abstract by Yager et al., is somewhat confusing. (how can

one have a floating chronology from 911-1992?; are tree-ring dates or calendar equivalent 14C dates being cited here?) This section on Alaska is quite dated (see Luckman and Villalba and several references by Wiles and Calkin cited therein).

16 2 This section needs to be reworked. The data presented for Klinakini Glacier

and Franklin Glaciers are presented and then queried without reaching any conclusion. Both indicate glacier advance after the dated materials and the comments qualifying these dates apply equally well to many other dates cited in this paper. (Lag time is ignored at several other sites in the discussion). The reporting of the Bridge Glacier site is incorrect. Ryder and Thomson only identify one advance here, not two and consider both 14C ages provide limiting dates for the same event. The till described is between the paleosol and the present surface not between two paleosols. Although scattered, there are several other papers on this region- Ryder 1987, Desloges and Ryder 1990, Clague and Mathews, 1992 etc - see Luckman and Villalba, in press).

16 As stated earlier, discussion of the Canadian Rockies should be included with western North America. There are also early LIA moraines on Mount Baker in Washington.

18 1 Rothlisberger and Geyh?.

19 1 1-2 Rationale for this statement?

20 1 1-2 See earlier discussion. The ice core data provide information about snow accumulation and climate- not necessarily glacier advances

20 1 end in-situ trees at what site? Again Thompson is referring to a climate event not a glacial event

20 Footnote 13 Based on what data? 1970 predates the 1976 Pacific Climate shift.

21 2 13-14 Again, is this bias? In my experience dating based on the oldest tree for most moraines has far smaller error terms than radiocarbon dating. In this specific case the moraine may be older but this does not justify the statement "approximate at best"

21 2 20 why is Rothlisberger's date of 1000-1220 cal AD acceptable in this circumstance but Ryder and Thomson's date of 1040-1210 (p16) not?

24 footnote 14 although the survey may have delimited glacier area, I assume it was an aerial survey !!

24 3 1 sub-fossil trees.

24 3 5 see comment on 21 2 20 above.

24 3 8 14C dates do not sample! Sample HV.xxx taken from a stump.....etc

26 footnote 16 see Gordon and Harkness, 1992 Quat Sci Rev, 11 697-709 for a comprehensive review

28 2 see earlier comments on ice core discussions.

28 3 4-5 what specifically is meant here? Warmer and cooler intervals for which dates?

29 2 5-6 see above. Lack of obvious period of significantly cooler temperatures?

30 2 1-2 But you don't present any "precise dates" in this table, nor are any of the calendar dendro dates from Alaska included . If this table is intended to be a summary should not it show all of the data being discussed?

31 1 3-4 The implication here seems to be that a 14C date from an in-situ log gives a more precise limiting date for the subsequent glacier event than date from a log that is not in-situ? Is this the case? Or is it that dates on wood are better calibrated than dates on soils, bones or other materials?.

32 1 4 Luckman 1995 I think.

32 1 10-11 These are not dates from moraines but dates from forests overridden by glacier ice. Are there any examples of moraines dated to the 13th century presented in this paper.

Table 10 is never referred to in the text. It needs a caption. Does 13=13th

century or 1300s?

33 1 1-3 NO. decreased temperatures or increased accumulation correlated with the

LIA have been identified in these cores.

This is not a very synthetic conclusion.

34 Barlow et al., 1997 delete in press

35 Bjork Antarctic

36 Corte CONICET not CONISET

36 Eglinton Font

36 Fushimi Initials

36 Fuhimi 1978 delete reference to 1977!

37 include Grove in press

38 Holzhauser 1998??

Dear Tim,

Thanks for your comments. Some responses to them are given below. I'll be too busy for further correspondance as I prepare for travel, leaving Friday morning for a week.

Since I will be away and unreachable through next wednesday. I would thus request that you and Keith correspond with my co-authors Ray Bradley (who should be able to respond upon his return from current travel on Sunday /Monday) and Malcolm Hughes on the revisions (please cc to me so I can read upon my return), as I will be unreachable.

I'm sure we can come up with something mutually agreeable to all of us with this piece, as is my goal with IPCC, as long as there is proper communication and mutual understanding by all concerned. Lets strive for this--choice of language is a nontrivial element...

best regards,

mike.

COMMENTS

One additional new comment:

0) 1st page, "In attempting to do this...Mann et al...exemplifies" is unacceptable language to us. We confront the very problems that are being discussed here, so it is a disservice to us to say our paper "exemplifies" these problems. It "exposes" or "confronts" would be fair language, but "exemplifies" is unacceptable.

responses to your responses to my original comments:

1) I'm not sure how to interpret your response vis-a-vis my original comments here. My point is that our use of southern hemisphere records in the reconstructions is fundamentally sound, from the point of view of some very basic principles of optimal interpolation, etc., and given the domain we are reconstructing, which is not NH only, although we diagnose NH from our pattern reconstructions as a key index. There is no basis for what sounds like

a criticism of our use of such data. I couldn't tell if you were agreeing with this or not from your comments.

2) The uncertainties are determined from the uncalibrated variance given a certain predictor network. The predictor network is unchanged from 1820 to present, so the verification period (1854-1901) unresolved variance is an independent check on the calibration period unresolved variance. Both gives numbers in the range of 30% for the NH mean temperature reconstruction, meaning that the error bars we determine from verification period are essentially the same as those we determine from the calibration period. IN this sense, the error bars as determined from calibration and verification are essentially identical, The bottom line, if we had used the verification period to estimate the error bars, the eye would barely see the difference.

There may be a considerable misunderstanding on your/Keiths part, regarding regarding what is actually shown by the spectrum of calibration residuals in our GRL paper. It does not in any way conflict with what I indicate above. What this particular diagnostic shows is that there is no evidence of any increase in unresolved secular variance (ie century-scale and longer) in our reconstructions at least back to 1600. In contrast, there is evidence that such frequencies are not as well resolved as higher frequencies with the sparser predictor network available before 1600. Our estimates of uncertainty TAKE THIS FACT *EXPLICITLY* INTO ACCOUNT. Our uncertainties estimates are made up of two components that add in quadrature, including a component of uncertainty in the lowest-frequency variability as estimated from the spectrum shown, and a component of the highest-frequency variability from the spectrum shown. These are approximated as a step-wise break in the mean (white noise) level of unresolved variance at the edge of the secular band. Unlike any previous study, we have actually estimated the increased uncertainty due to the loss of low-frequency variability as it can best be estimated, and this is explicitly incorporated into our error bars, which is why those error bars expand considerably before 1600. This is discussed in the GRL paper, and is a VERY important fact. It would be very unfortunate if this fact were misrepresented!

3) I'll leave this to Keith and Malcolm to discuss (Malcom?). I think it is pretty clear in the paper what our assumptions are here, and what the justification is of those assumptions. There is of course room for differing opinions on this stuff, as it is all somewhat speculative, and we indicate that this is so in our paper.

4) good enough

5) I really doubt that the 2000 year trend is meaningful and, unlike the results we have shown, there is no confirmation that these 3

sites accurately reflect northern hemisphere mean temperatures to any reasonable level during the modern era.

Work by us and others looking at similar data would suggest that series in such regions are not adequately representative of the largest-scale trends. There is, further, no verification of the frequency-domain attributes pass any satisfactory test. For these reasons, I have informed Julia Uppenbrink directly that I don't believe this series should be shown in this context. I agree it is an important series, and it will be appropriate to discuss it in IPCC. But it should not be considered on a par with more statistically-verified true Northern Hemisphere mean temperature reconstructions, and it is very misleading to show it along with the NH mean reconstructions. The 2000 year trend runs absolutely counter to everything we know about the mid holocene. Extratropical Northern Hemisphere summer temperatures should have been at an absolute peak 4000-6000 ybp, and the 2000 year trend *ought* to at least be heading in that direction. The fact that it doesn't, and that the trend hasn't been verified in the sense discussed above, causes me real concern. It would be misleading to argue we have any reason to believe that NH mean temperatures have done what that series does 2000 years back in time...

Re, the adjustment of the series, I believe it is fundamentally unsound. Essentially, agreement over the period we can best constrained (20th century) has been sacrificed for agreement during the period we can't constrain, apparently for the sake of getting the different series to align during the 19th century. Please download the figures I have prepared for the latest IPCC report.

<ftp://eclogite.geo.umass.edu/pub/mann/IPCC/nhemcompare-ipcc.gif>

OR

<ftp://eclogite.geo.umass.edu/pub/mann/IPCC/nhemcompare-ipcc.ps>

You will see how I have aligned the series based on a 1961-1990 reference period for the instrumental series, and a 20th baseline adjustment for the alignment of all series. To me, this is the most reasonable adjustment of the series if they are to be shown together. It also shows the different that latitudinal variations make EXPLICITLY by showing the difference between our TRUE (0-90 lat weighted) NH annual mean temp series, and an extratropical (30-70 deg lat) average from our pattern reconstructions, which approaches quite closely the Overpeck et al '97 and Jones et al '98 series. Seasonal distinctions then the key remain difference. This is, I believe, the best approach to the comparisons, and the one I will favor

in IPCC.

The alternative is that true NH mean temperatures and extratropical NH mean temperatures must be shown on separate plots, because adjusting them the way Keith has provides a misleading picture, and one that I don't believe can be justified for the purposes of IPCC, regardless of what you choose to do with your Science piece.

Cc: mhughes@ltrr.arizona.edu, rbradley@geo.umass.edu

Dear all,

Ray accurately (though w/ not the same level of detail) obviously recapitulates my main concerns here. As for the one area of disagreement (not understanding the reason for expecting an overall cooling during the 1st millennium), I'll refer Ray to the appropriate areas of his Paleoclimatology text book, and show him some additional recent work relevant to this, upon my return.

Thanks again to all for working to make the final product one we can all be happy with.

best regards,

mike

Reply-to: grissino@VALDOSTA.EDU

Dear Steve,

AZ510.crn is a bristlecone pine chronology. I suspect the others you are working with are ponderosa pine or Douglas-fir. In this region, these lower-elevation species have quite a different response to climate than the bristlecone. I haven't worked with the AZ510 chronology, but I would guess that bristlecone tree growth at this site would be favored by warm winter temperatures and perhaps somewhat drier conditions, while the ponderosa and Douglas-fir do well under cool, wet winter conditions. This may be the reason for your poor correlations.

Reply-to: grissino@VALDOSTA.EDU

Steve:

I've had some experience with bristlecone pine on the San Francisco Peaks and you are correct in noting their lack of correlation with precipitation records and with other precipitation sensitive tree-ring chronologies like Slate Mtn. Ponderosa. There is no "problem" with the AZ510 chronology; it is, as suggested by Dave, Connie, and Jim, a chronology constructed from trees whose growth is not primarily limited by precipitation. Site location and tree species are critical when comparing chronologies and evaluating climate - tree growth relationships.

We've collected in the Peaks recently as part of an ongoing archaeological and paleoclimate project and have built a chronology extending back to 663 BC, more than 1200 years longer than the AZ510 chronology collected by Don Graybill in the early 1980's. We're working on a temperature reconstruction from this chronology that should prove to be a valuable addition to the already extensive archive of southwestern USA paleoenvironmental research.

[Mitchell, John FB] 3.471 in longwave, 3.26 when shortwave also
taken into account. Unfortunately modellers do not always make clear how
they have estimated their CO₂ forcing.

> and

>

> b) why the forcing curves in the plot William Ingram sent show higher

[Mitchell, John FB] HadCM2 is 1%/year increase in CO₂ which is only
approximately equivalent to IS92a. Hadcm 3 is "95a" - in fact "95a" I think
differs only from in the conversion of the 92a emissions to concentrations,
so strictly speaking is not an emissions scenario. As far as I know, Tom
never did explain why his concentrations in 1995 were different from the

ones Jonathan and I derived using his 1992 model- I think CH4 lifetimes and the CO2 sink were the main factors.

> 3.47Wm⁻² - see a)). Surely this should lead to faster warming in CM3 cf.
> CM2?

[Mitchell, John FB] See above - HadCM2 uses 1%/year increase in CO2, which gives a greater forcing than HadCM3, even after the effect of explicit trace gases is added in.

(about 0.5Wm⁻² by 2100). The greater climate sensitivity does not make as big a difference as one would expect. The difference in CO2 forcing per doubling is not the issue- the net forcing is, and that has been calculated taking the difference in CO2 response into account

Maybe I have misinterpreted something here.

Subject: Re: CRU Board

Date: Tue, 04 May 1999 09:08:24 +0100

Mick,

CONFIDENTIAL

I think I'm missing out on something here (refer also to Keith's email where he talked about "CRU being railroaded by ENV"). My recollection was that it was agreed that I should approach Reading to see if they are up to anything & sound out if they might be interested in talking about a joint bid. The suggestion may have been mine originally, but I do not have absolute recollection over that. Southampton have approached us via the Registrar and via Peter Liss. As far as I am aware, nobody from UEA has approached them (although I have certainly argued with Jean that we should at least talk with them).

I now have a leaked document which spells out some of the research councils' thinking. I will get a copy over to CRU today. Please keep this document within the CRU5, since it may compromise the source. NERC and EPSRC are signed up. ESRC are not yet. Given the EPSRC stake, it will certainly be useful to get RAL etc involved. The funding might be 2million per year. That might imply that the Councils favour multi-site, clusters, etc, but they stress they have no preconceptions.

Given some of their requirements, the JIF bid may be useful.

An important requirement seems to be to attract an "internationally renowned and charismatic scientist" to be overall Director. Do you think we should sound out Schneider? Watson? ??

Hi Keith,

Thanks very much for the update. Sounds like everything should be good here. I'm sorry If I might have seemed to over-react, but it was just to make sure we avoided the scenario of last year where we had to end up publishing a followup letter because we and Phil hadn't had adequate communication before the piece was published. I'll look forward to seeing the piece in print. It sounds like you guys have a done a very good job. Indeed, Tim and we had a very constructive dialogue about things in your absence. Will be in touch.

best regards,

mike

p.s. I mentioned to Phil it would be nice to get at least one spatial pattern of your summer dendro temperature estimates into IPCC, along with a pattern or two from our multiproxy recons. I haven't heard back to Phil, but perhaps you can make a specific suggestion, and send me an appropriate postscript file? It's not too late to get this to Chris Folland for inclusion in the initial draft. Thanks in advance...

Hi Phil,

SOrry that you have taken such a negative spin from this. I had hoped it was all resolved pretty amicably, and emphasized to Keith and Tim that I was being perhaps overly picky this time PRECISELY to avoid the misunderstanding that happened last time around w/ Science.

Trust that I'm certainly on board w/ you that we're all working towards a common goal. That is what is distressing about commentaries (yours from last year, and potentially, without us having had appropriate input, Keith and Tim's now) that appear to "divide and conquer". The skeptics happily took your commentary last year as reason to doubt our results! In fact, your piece was references in several commentaries (mostly on the WEB, not published) attacking our work. So THAT is what this is all about. It is in the NAME of the common effort we're all engaged in, that I have voiced concerns about language and details in this latest commentary--so as to avoid precisely that scenario.

Please understand the above to be a complete and honest statement about the source of my concerns. It really doesn't have anything to do about who did what first, etc. I trust that history will give us all proper credit for what we're doing here.

The millennial-scale trend issue appears to be a source of contention. Malcolm can address the replication issue better than any of us--it's not a problem w/ our reconstruction. Furthermore, WE HAVE EXPLICITLY TAKEN INTO ACCOUNT THE LOSS OF LOW-FREQUENCY VARIANCE IN OUR ESTIMATES OF UNCERTAINTY. I don't know how many times I need to stress this. It is of fundamental importance in framing our conclusions. Our own analysis convinces me that things are already quite uncertain a millennium back in time. With regard to longer timescale variations, the evidence is all over the place. At EGS I saw some convincing evidence that many new paleo proxies indicate steadily decline at least over several millennia, and so do, in large part, the available long borehole estimates (though we should all take that w/ a good dose of NaCl). So I'm skeptical of estimates more than a millennium back in time until we have multiple proxies we can trust at that timescale, and can verify somehow the DC component of the estimates, or at least replicate them. This was my concern about the latest 2000 year recon that was shown.

You are right, the Milankovitch forcing argument is ONLY A NULL HYPOTHESIS. I hope I haven't argued anything more than that. That our millennial scale trend, which

we reasonably trust, and have some idea of the uncertainties in, is in line w/ that null hypothesis is information that cannot be ignored. That Kutzbach, Berger, and others are showing increasingly convincing model integrations over several millennia suggesting this, is more evidence. In the real world, anything *could* have happened. But lets not loose site of the appropriate null hypothesis here.

I hope the above clears things up somewhat. I'm sorry things have been construed in more negative light than I had ever intended. Call me anytime to discuss, here at the office (not sure how well our schedules overlap though).

Thanks, and sorry for the miscommunication here,

mike

Hi Phil,

Thanks for your message. I'm with you 100%, and honestly am very much looking forward to moving towards close collaboration between us. I've already talked a bit w/ Tim about those plans and the possibility of him spending some time in Charlottesville, etc. Will be in touch w/ you guys soon about trying to solidify some of these plans...

Yes, I will be in the Lion's den, so to speak. Not sure how much must stands behind his roar though... We do have to deal w/ the skeptics here somewhat directly. At least, to the extent that I do presentations on capitol hill for USGCRP (I do one w/ Jim Hansen and Malcolm on the 17th of this month), I'm a bit in the fray. Mostly, though, I've been trying to help Mike McCracken and company behind the scenes. We all know what happens when a U.S. scientists becomes a thorn in the side of big business...

Anyways, I'm really happy that the air is cleared. More soon,

mike

Mike,

Just back from two weeks away and from discussions with Keith and Tim and some emails you seem quite pissed off with us all in CRU. I am somewhat at a loss to understand why. It is clear from the emails that this relates to the emphasis placed on a few words/phrases in Keith/Tim's Science piece. These may not be fully resolved but the piece comes out tomorrow. I don't want to open more wounds but I might by the end of the email.

I've not seen the censored email that Ray has mentioned but this doesn't, to my way of working, seem to be the way you should be responding - ie slanging us all off to Science. We are all trying to work together for the good of the 'Science'. We have disagreements - Ray, Malcolm, Keith and me have in the past, but they get aired and eventually forgotten. We have never resorted to slanging one another off to a journal (as in this case) or in reviewing papers or proposals. You may think Keith or I have reviewed some of your papers but we haven't. I've reviewed Ray's and Malcolm's - constructively I hope where I thought something could have been done better. I also know you've reviewed my paper with Gabi very constructively.

So why all the beef now ?

Maybe it started with my Science piece last summer. When asked to do this it was stressed to that I should discuss how your Nature paper fitted in to the current issues in paleoclimatology. This is what I thought I was doing. Julia Uppenbrink asked me to do the same with your GRL paper but I was too busy and passed it on to Keith. Again it seems a very reasoned comment.

I would suspect that you've been unhappy about us coming out with a paper going back 1000 years only a few months after your Nature paper (back to 1400). Ray knew all about this as he was one of the reviewers. Then the second Science comment

has come out with a tentative series going back 2000 years. Both Science pieces give us a chance to discuss issues highly relevant to the 'science', which is what we have both tried to do.

Anyway that's enough for now - I'll see how you'll respond, if at all.

There are two things I'm going to say though :

- 1) Keith didn't mention in his Science piece but both of us think that you're on very dodgy ground with this long-term decline in temperatures on the 1000 year timescale. What the real world has done over the last 6000 years and what it ought to have done given our understanding of Milankovic forcing are two very different things. I don't think the world was much warmer 6000 years ago - in a global sense compared to the average of the last 1000 years, but this is my opinion and I may change it given more evidence.
- 2) The errors don't include all the possible factors. Even though the tree-ring chronologies used have robust rbar statistics for the whole 1000 years (ie they lose nothing because core numbers stay high throughout), they have lost low frequency because of standardization. We've all tried with RCS/very stiff splines/hardly any detrending to keep this to a minimum, but until we know it is minimal it is still worth mentioning. It is better we (I mean all of us here) put the caveats in ourselves than let others put them in for us.
- 3) None of us here are trying to get material into IPCC. I've given you my input through the review of the chapter in Asheville. I may get a chance to see the whole thing again at some stage, but I won't be worried if I don't.

I can't think of a good ending, but hoping for a favourable response, so we can still work together.

Cheers
Phil

Mike,

We'll differ a bit on a few points, but let's wipe the slate clean and get back to improving our estimates of past changes over the last millennium.

I must admit to having little regard for the Web. Living over here makes that easier than in the US - but I would ignore the so-called skeptics until they get to the peer-review arena. I know this is harder for you in the US and it might become harder still at your new location. I guess it shows though that what we are doing is important. The skeptics are fighting a losing battle.

Cheers

Phil

Hi, David,

I don't think that Antarctic is the principal source of differences. When we compare only the common areas it doesn't really come into play. There are areas in Mexico and Northern Africa that seem to contribute more to the differences. Makiko will put the plots that you requested at <http://giss.nasa.gov/~cdmss/Parker>

Regards, Jim

>

>We are trying to understand the cooling of your data relative to Phil Jones's in the Southern Hemisphere during the 1990s (Table 1 below) in the annual series you sent to Ian Macadam. Plots of these were shown at the IPCC meeting in Asheville in March and showed the same relative cooling, but Figure 2 of your mailed illustrations does not show it. I note that the comparison in Figure 2 was made over the common area. If you use all available grids, do you get the relative cooling in the GISS dataset? I expect you will, because I have been perusing your web site and have noted that most recent years are cold over Antarctica in your dataset. This could be the focus of the problem, as your stations (with 1200km influence) will have more weight than Phil's unless you use common grids.

>

>As an aside, recent cooling over Antarctica could be partly forced by ozone losses, though I note that the cooling is strongest in March-May, not in Sept-Nov when the ozone hole occurs. If Antarctica cools, there will be consequences for Southern Hemisphere atmospheric circulation patterns, conceivably even contributing to the recent cooling of marine air temperature

I want to make one thing really clear. We ARE NOT supposed to be working with the assumption that these scenarios are realistic. They are scenarios-internally consistent (or so we thought) what-if storylines. You are in fact out of line to assume that these are in some sense realistic-this is in direct contradiction to the guidance on scenarios provided by the synthesis team.

If you want to do 'realistic CO2 effects studies, you must do sensitivity analyses bracketing possible trajectories. We do not and cannot not and must not prejudge what realistic CO2 trajectories are, as they are ultimately a political decision (except in the sense that reserves and resources provide an upper bound).

'Advice' will be based on a mix of different approaches that must reflect the fact that we do not have high confidence in GHG projections nor full confidence in climate system model projections of consequences.

To: Mike Hulme <m.hulme@uea.ac.uk>
Subject: Re: CO2 concentrations
Date: Wed, 19 May 1999 16:21:51 -0600 (MDT)
Cc: Mike MacCracken <mmaccrac@usgcrp.gov>

Dear Mike,

Yes, I am aware of the confusion surrounding what the Hadley Centre did and why. It is even messier than you realize. I have forcing data sets (more than one!) from Jonathon Gregory that differ from the numbers you gave in your email!! The Hadley people have clearly screwed things up, but their "errors" don't really matter given all of the uncertainties. I didn't mention this because I thought that opening up that can of worms would confuse people even more.

In my view (trying to keep things as simple as possible), the key points are these:

- (1) The HadCM2 run purports to be IS92a, and it is a good approximation to this.
- (2) Their use of 1% compounded for CO2 **is** a reasonable approximation to the IS92a GHG forcing (which, itself, is uncertain).
- (3) The climate model output is also uncertain.
- (4) The pure CO2 input to IS92a is what I have distributed from the Bern model.
- (5) Hence, the best and simplest combination is to use HadCM2 climate output with these (point (4)) **a priori** defined "pure" CO2 concentrations for IS92a.

On Wed, 19 May 1999, Mike Hulme wrote:

From: Tim Osborn <t.osborn@uea.ac.uk>
To: Orson Vandeplasseche <ovdplasseche@mail.wesleyan.edu>
Subject: Re: tree rings
Date: Thu May 27 10:57:56 1999
Cc: k.briffa@uea

Dear Orson

Very sorry for such a slow reply.

The individual curves (Tornetrask, Taimyr and Yamal) have not been calibrated against their local temperature records yet, and so only exist as standardised (or normalised) anomalies.

For the calibrated Tornetrask record of Briffa et al. (1992), the calibrated reconstruction made use of both tree-ring width and tree-ring density and so it will look different to the ring-width only record shown in the PAGES newsletter recently. For the earlier extension to this record, only ring-width will be available - which is why the calibrated record cannot be simply extended with the new data. Instead, a new calibration needs to be made, using ring-width only. This hasn't been done yet, and - while it *might* be a simple linear regression - sometimes ring-widths from one year and from the previous year are used together as predictors, so I cannot guarantee that it will be a simple rescaling of the uncalibrated curve. Nevertheless, the uncalibrated curve *is* correlated with summer temperature, so it certainly provides useful information.

The average of the three series was calibrated *after* they were averaged, and was calibrated against the April-September mean temperature over all land north of 20N. This was purely for comparison with the other curves shown in our Science piece; for this curve, this region is by no means the optimum, and the temperature anomalies would no doubt differ in magnitude if a regional temperature from northern Eurasia had been used instead. This offers one explanation of why the 650-750 warming differs from Briffa et al. (1992). The second is that only ring-width has been used. The third reason is that it is the average of 3 curves - if the other two don't show the warming, or not as strongly, then of course the signal will be less pronounced in the average. So, you can still use the Briffa et al. (1992) calibration - it is certainly not wrong.

Hope this helps with your choice of what to use.

We will send you a reprint to your Middletown address when they arrive. I am now going to mail you hard copy (black & white) of the Tornetrask uncalibrated ring-width record (annual and 50-yr smoothed) from the PAGES article, and also a hard copy of the calibrated northern Eurasia record from the Science paper. The northern Eurasian record should preferably be referenced using both Briffa & Osborn and Briffa et al.

Best regards

Tim

To: "Folland, Chris" <ckfolland@meto.gov.uk>
Subject: RE: VARIANCE PROBLEM
Date: Thu, 10 Jun 1999 15:48:05 +0100
Cc: d.parker@meto.gov.uk,t.osborn@uea.ac.uk

Chris,

Sorry to be flooding you with another email, but I was discussing this with Tim. Tim reminded me of a paper that he'd written in that well known journal Dendrocronologia ! I've sent down a copy of the proofs to you both. The paper has been in press for the last 2 years ! This must be the slowest journal in the world. This has some more theory in it and some variance corrections for tree-ring and temperature series.

We are going ahead with the method I've outlined over the last few emails. Tim and I have modified a couple of things slightly :

1) Using the present combined dataset (Jones, 1994 and Parker et al. 1995) we will calculate monthly rbars for each 5 by 5 box. The grid-box time series will be filtered with a 30-year Gaussian filter. rbar will be calculated from the residual grid-box time series. Tim reckons that a longer filter is better (an analysis in the paper). He suggests 40 years, but this involves more problems with the ends, so we'll go with 30. I don't think 20,30,40 will make that much difference to the rbar values.

We are using the combined dataste for the estimation as this should produce better rbar values around coasts and islands. If we used the land only dataset we would have real problems with isolated islands and with some coasts (where all neighbouring boxes will be in one direction from the coastal box).

2) Having got fields of the monthly rbars we'll then apply the formula to the land-only dataset. As you're doing something similar with the marine dataset, we can remerge the two variance corrected datasets using David's merging (growing land and neighbour checking) program.

3) We will then write this up as a small paper for GRL, about the land only results. Both of you can be on this if you want. We can decide later what to do about the merged dataset.

4) applying the correction in real time in the future will mean that we will always be slightly changing approximately the last 15 years data - because of the filter end effects. Best would seem to be to maintain the present version we have and apply this variance correction every few years (eg the IPCC cycle !).

Cheers
Phil

Paul

I have been told PRESCIENT is positive. It has been factored into NERC finances -for the full 8 million I believe. No official written statement has been declared as far as I know but someone from NERC visited here while I was away in Russia last week and talked of a first call for proposals in April 2000. At present this is all I know. Will keep you informed if I here more.

best wishes
Keith

Subject: Density data from Polar Urals
Date: Wed, 16 Jun 1999 16:32:32 +0500
Reply-to: "Stepan G. Shiyatov" <stepan@ipae.uran.ru>

Dear Keith,

I am reminding your promise to send me raw density data from Polar Urals remnants of larches as soon as possible, as I must prepare samples for Fritz until the end of June. Leonid Agafonov will bring them to Slovenia to Fritz.

Tomorrow I will lie down in hospital for 7-9 days, as I get the infection from a tick in Iremel area, not encephalitis, but a new kind of infections from ticks, namely "lime-borrelious" (I do not know its name exactly in English). The sign of this disease is red field approximately 5-8 centimeters in diameter around the point where a tick bite a body. This place itches greatly. If you have such characteristics, you must apply to doctor. This disease is not so dangerous as encephalitis and can be easy recovered from antibiotics. I hope that your tick did not contained such infection.

I wish you the best.

Sincerely yours,

Dr. Stepan G. Shiyatov

Subject: Re: Density data from Polar Urals
Date: Fri Jun 18 11:21:10 1999

Stepan

I am attaching the raw density measurements (max. latewood den.) for the Sob River site as we extracted them from Fritz data bank. The format is Tucson like (index) except for a different header on each sample series. For your purposes the start and end date of each series are shown as the 2 I4 fields in columns 5-12 of these identifier lines. I hope this is all you need. You may also refer to Figure 2a in our paper in the NATO ASI Volume edited by Phil. The article on Low Frequency Signal problems that you are a co author on. This Figure shows the number of density samples through time in this chronology - very low before 1200 and between 1400 and 1600!!

I am sorry to hear of your tick infection. This is no laughing matter and you should ensure that you are well treated and rested. As of yet I have no problems other than worrying about how we will organise future proposals to the EU. Thankyou again for your hospitality and the warm reception from your excellent group. I sincerely hope we will be able to continue our collaboration for many years to come. I hope too that Eugene also feels committed to this working relationship. Perhaps he was tired but I got the impression his priorities were not so much concerned with our work.

I await detailed description of the full network - locations and correspondence with the density network positions and names - that I believe Valerie will work on. Perhaps the outline and draft of something from Rashit would also be forthcoming soon.

Meanwhile I send my best wishes to you and I await news of your continued health

Keith

Subject: Plan of action for Chapter 2
Date: Mon, 21 Jun 1999 13:12:34 -0400

Below is the text and attached is a file in MSWord regarding a plan of action for Chapter 2 leading up to the IPCC Meeting in Arusha, Tanzania.

June 21, 1999

Dear Lead Authors and Key Contributors,

This note is to outline a plan of action for Chapter 2 leading up to the IPCC meeting in Arusha, Tanzania to take place 1-3 September. As you know, we are now in the midst of a "friendly review" from our colleagues of the strawman draft of our chapter. We expect to receive comments from these reviews through middle or even late July. These reviews will include some from people other than our nominated reviewers, like Sir John Houghton, from whom we have just had a brief review. Please check regularly with the Tar02.meto.gov.uk email site to cover this aspect.

Accordingly we ask each of the individuals listed below to revise the draft section as suggested below, and to indicate their response to reviewer's comments. The first person listed is to take the lead, and individuals with an asterisk by his name are to prepare the material for presentation in Arusha. We would ask that a provisionally revised part of your chapter be completed by 20 August and emailed to Tom Karl or placed on the website so that Sylvia Decotiis can create a new version of Chapter 2 for Tom to bring to Tanzania. Tom will bring one paper copy of the provisional new "Arusha" version of chapter 2 to Tanzania, and a complete series of electronic files which can be input to PCs via 1.4MB floppy disks. It would be a considerable advantage for attendees to bring portable PCs, though we expect some IPCC PCs to be available at the Arusha International Conference Centre.

Chris Folland will be leaving for Tanzania early (24 Aug) whereas Tom Karl

will still be available until 29 Aug for urgent interactions. We will decide later as to whom, and how many of us, should actually make presentations, noting that Hans Oerlemans is not likely to be present.

But

all attendees be prepared, and bring appropriate visual material and of course, further suggestions. We have listed assignments next to each section.

Section 2 ----- Tom Karl* and Chris Folland* Executive Summary ù
total
revision and update
Section 2.1 ---- Chris Folland* Changes needed regarding uncertainty
guidelines
Section 2.2.1 ---- Chris Folland* Okay for now
Section 2.2.2 ---- David Parker, Phil Jones, Tom Peterson, Chris Folland*
Length okay, but reduce number of figures.
Section 2.2.3 ---- John Christy* Check for accuracy
Section 2.2.4 ---- John Christy* Check for accuracy
Section 2.2.5 to 2.2.6 ---- Oelermans*, Nick Rayner, John Walsh, David
Robinson, Tom Karl and Chris Folland. Glacier section needs to be updated
Section 2.2.7 ---- Oelermans, Tom Karl* Check for accuracy
Sections 2.3 through Section 2.3.5---- Mike Mann*, Phil Jones Reduce in
size by about 10%
Section 2.4 through Section 2.4.5 ----Jean Jouzel* Reduce in size about
10%
Section 2.5 through 2.5.4 ---- Jim Salinger*, Pasha Groisman, Mike Hulme,
Wang. Provide a better context for why this section is important, more on
upper tropospheric water vapor if possible
Section 2.5.5 ---- Steve Warren, Dale Kaiser, Tom Karl* Add new analyses
of
cloud amount
Section 2.5.6 ----Jim Salinger*
Section 2.6 through 2.6.6 ----Jim Salinger*, George Gruza, Alynn Clarke,
Wang. Reduce in size by at least 50%. Identify a rationale section at the
beginning. IPCC 1995 will help here. Some material may go elsewhere. May
need to consult Mike Mann or Jean Jouzel. Please send revised section to
Chris Folland to finally review (even if not complete) by 16 August.
Chris
will feed back changes to Jim by 23 August. Jim Salinger should interact
with Chris during this work too. Jim should prepare presentational
material
Section 2.7 through 2.7.4 ----David Easterling, Pasha Groisman, Tom Karl*
Review for accuracy
Povl Frich: please interact and be prepared to present extremes parts.
Jim
Salinger: you may have more material on extremes in the South Pacific.
Please feed this to Tom Karl and Povl Frich.
Section 2.8 ---- Tom Karl, Chris Folland* Develop a summary, including
strawman cartoon

In addition we have about twice the number of figures that will be
allowed

so everyone should identify figures that can be removed or combined to
reduce the size. The latter can sometimes be very effective. At the

present time we are about 1/3 over our word limit so everyone will have to respond to the reviewers (often requesting more), and yet being more judicious in the words we use. Please consult the 1995 IPCC Report as a guide.

Please do not hesitate to comment on these plans, preferably as soon as possible, so that holiday arrangements etc do not cause problems.

Cheers and thanks,

Chris and Tom

Dear Keith,

I recovered from tick's infection, at any case I do not have high temperature during the last week. I hope that your health is also good. Now I am preparing for field work.

I selected 32 new samples of dead larch trees from the Polar Urals and sent them to Fritz via Leonid Agafonov. A new version of the chronology will be up to 170 years longer and a better replicated between 1400-1700 AD.

The hard disk is working perfectly, thank you very much.

My best wishes to your family and Phil.

Sincerely yours,

Dr. Stepan G. Shiyatov

Investigations that Contribute to the NASA Earth Science Enterprise's
Modeling and Data Analysis Research

General Information

Solicitation Number: NRA-99-OES-04
Response Date: Sep 27, 1999

Description

NASA is soliciting proposals for investigations that will contribute to modeling and data analysis research that is supported by NASA's Earth Science Enterprise. This NRA solicits proposals directed to the interests of disciplinary research and analysis, interdisciplinary science, and data analysis programs that include global and regional modeling activities and large-scale data analysis, especially model-driven analysis. It also solicits proposals from instrument science teams and/or guest investigators being newly competed or re-competed in which global and regional modeling and/or model-driven data analysis constitute major elements of the proposal. This NRA is expected to result in research funding of approximately \$65 million over three years. The individual program elements included in this NRA, and the responsible NASA Program Managers are:

Program Element

Manager

- a. Global Modeling and Analysis Program (GMAP) K Bergman
- b. Atmos. Chemistry Modeling & Analysis Pgm. (ACMAP) J Kaye
- c. Phys. Oceanogr. Research & Analysis Pgm. (PORAP) E Lindstrom
- d. Ocean Vector Winds Science Team (OVWST) E Lindstrom
- e. Pathfinder Data Set & Associated Science Pgm.(PDSP) J Dodge
- f. EOS Interdisciplinary Science Program (EOS/IDS) J Dodge

In keeping with overall NASA goals and those of the Office of Earth Science, research supported by this NRA will be directed toward demonstrating successful use of data from satellite observing systems, in conjunction with other kinds of data, to improve models and assimilation systems for the Earth system or one or more of its components.

Participation in this program is open to all categories of domestic and foreign organizations, including educational institutions, industry, non-profit institutions, NASA centers, and other U.S. agencies. In accordance with NASA policy as described in Appendix C, all investigations by foreign participants will be conducted on a no-exchange-of-funds basis, i.e., investigators whose home institution is outside the United States cannot be funded by NASA. Proposals may be submitted at any time during the period ending September 27, 1999. Proposals submitted to NASA will be evaluated using scientific peer review. Proposals selected for funding will be announced in November, 1999.

All prospective proposers are strongly encouraged to submit a letter of intent (LOI) to propose to this Announcement by August 27, 1999. This letter should contain a brief description of the research to be proposed. Please see Appendix E of the NRA for details.

Ed

to be really honest, I don't see how this was ever accepted for publication in Nature. It is a confusing paper that leaves me asking what actually have they done and what is the so-called testable Hypothesis of which they speak. Why didn't they do the testing? Yes Sob river is the Polar Urals site and I don't know why they get the results they do for it. Their precip. trends are dubious and our detailed regional response functions do not show a significant effect of high precip. in winter. I really have not had time to fully digest their message but I can't see why either they or Nature did not ask my opinion of it. My instinctive first reaction is that I doubt it is the answer but we do get results that support a recent loss of low-frequency spring temperature response in our data that may be consistent with their hypothesis of prolonged snow lie in recent decades. I have not spoken to Iain yet about the isotope data but I will. If you get any detailed thoughts on the Nature paper please let me know, as I don't know how to respond, if at all.

best wishes

Keith

COMMENTS ON CH. 13 (SCENARIOS) FROM TOM WIGLEY
(Page and line numbers are from the May 14 zero order draft.)

Dear contributors to Ch. 13,

Here are my comments on your chapter. I think you all know me well enough that you will not be offended by my occasional bluntness. The chapter needs a lot of work (not surprisingly), but it has at least touched most of the bases. It suffers from a lack of overview perspective, making the detail hard to wade through. I was disturbed by the lack of credit given to MAGICC/SCENGEN, since this software already addresses many of the key issues that arise in scenario development.

Apologies for not proof reading this. By the time I got to the end of typing it, I'd had enough.

- Page 3 (lines 86-89) : Critically, this information doesn't give a full assessment of uncertainties.
- 3 (110-115) : Sentence too long.
- 3 (117) : State 'illuminate uncertainty' earlier, since this is a primary purpose of, e.g., MAGICC/SCENGEN.
- 3 (118) : 'indeterminate' is far too strong.
- 4 (124-125) : Not clear.
- 4 (155) : What is 'integrated assessment'? Define and/or explain earlier.
- 5 (170) : Clumsy grammar.
- 5 (171-172) : Silly! Scenarios per se do not have ANY uncertainty associated with them, by definition. They are, however, a very (if not the most) useful tool for assessing and quantifying uncertainties. For example, a primary purpose of MAGICC/SCENGEN is to quantify uncertainties. Major text revision is needed to

clarify this point.

Part of the problem here is that the boundary between scenarios and predictions/projections is indistinct (as is the distinction between predictions and projections -- this too needs to be clarified). One could argue that 'scenarios' developed using MAGICC/SCENGEN are actually better predictions of some aspects of future climate change than any O/AGCM results. Certainly, 'scenarios' based on scaling are much more than just scenarios as defined here -- they are true predictions, based on some assumed scenario (this is the correct word here!) for future emissions.

Substantial work is required to the present text to clarify these issues -- they are the crux of the matter.

5 (178-179) : Note earlier that scenarios (a word I will continue to use even though it may be inappropriate in many cases) usually define CHANGES in climate. They are not, in these cases, 'scenarios', but 'scenarios of change'. Strict (i.e., absolute) scenarios are then constructed from them by adding the changes to a baseline climatology. This needs to be explained up front.

5 (187) : Delete '(and art)'. This is a derogatory term, likely to be misinterpreted/misrepresented.

6 (220) : Comma after 'scenarios'. The text contains many stylistic and grammatical errors (the most common being the failure to isolate parenthetical clauses). I will assume that someone with a better grasp of grammar will catch all these at some stage, so I will not comment further on them.

6 (225+) : A critical item missed here is inter-variable consistency. Later, consistency between climate and CO2 is mentioned; but there is no mention of consistency between, e.g., temperature and precipitation, etc. This is a major issue!

7 (257) : Instrumentally-based analogue scenarios were first introduced by Wigley et al. (Nature, 1979). Credit should be given. Also, the USDOE 'State of the Art (sic)' reports (1985) and the Bolin et al. SCOPE report (1986) both review this and other methods. This reviews should be cited.

7 (267-268) : What does 'extrapolating ...' mean?

7 (296) : Wigley et al. (1979) should also be cited here.

8 (306) : Nevertheless, they may do a better job of getting the inter-variable correlations 'right' than GCMs!

8 (315) : Delete 'questionable'. This word is entirely unnecessary here. More importantly, the authors need to be more careful in their choice of words, since there are many critics out there who

will be looking for things that can be taken out of context, misinterpreted, or misrepresented.

8 (344-345) : Control run? So what? This is only relevant if the control is used in scenario development. This raises the issue of 'Definition 1' versus 'Definition 2' for defining climate change (a terminology introduced by Santer et al., 1994, JGR). (Later, this difference is attributed to Cubasch et al., but it was first clearly enunciated by Santer et al.) The difference is whether or not one subtracts the control from the perturbed result. More needs to be said about this. It is often assumed that subtracting the control will remove any spurious drift in the perturbation experiment. This, of course, is clearly wishful thinking, both a priori, and as shown by Raper and Cubasch (1996). Basically, there is no way to reliably remove drift in a perturbation experiment; which makes it all the more important to have drift-free models. Flux adjustments do not necessarily remove drift -- just look at some of the ECHAM control-run results. There are some very important issues here, central to the use of O/AGCMs in scenario generation. They need better coverage. More is said later, but this is still inadequate.

9 (357) : Yes, they can be different, but so what? The issue is whether the differences are statistically significant. To my knowledge, no one has addressed this issue properly.

9 (358) : I'm sure (at least I hope) you don't mean 'observed'. The issue is the difference between the equilibrium PATTERNS of change and the MODELLED (NOT 'observed') transient patterns of change.

9 (to 361) : You've missed the most important point! The advantage of an equilibrium result over an O/AGCM result is that the former is pure signal.

9 (to 376) : The Definition 1 versus Definition 2 issue is relevant here.

9 (379) : Please don't propagate garbage. The issue here is natural internally generated variability. There is no need for such variability to be chaotic, so you should eschew use of this word.

9 (to 387) : I presume here that you are talking about O/AGCMs. You should not use just 'GCM' -- you must be specific. Also, you've missed some vital points: the natural internal variability problem (i.e., output is signal plus noise -- noted elsewhere, but must be stated here); and the model-specific nature of the climate sensitivity.

10(399) : Please give credit to the first work on this (Santer

- et al., 1990). I should point out that this was actually my idea.
- 10(404-406) : Totally unclear.
- 10(420-421) : Poor wording. Should be '.. to which changes are added'.
- 10(423) : Delete 'appropriate'.
- 10(429) : Insert 'based' after 'period'.
- 10(431) : 'weather generators' comes as a non sequitur here. In any event, you haven't said what they are!
- 10(435-437) : So what? The issue is what period one is measuring the impacts from. In most cases it will be some nominal 'present-day', so the baseline climatology must refer to the same period. Whether or not the period has some sulphate effect in it is utterly irrelevant.
- 10(437-438) : What garbage. See above.
- 11(448-450) : More garbage -- think about it! The reason 1990 is not so useful as a reference 'period' is because the impacts variable is probably not adequately definable over a single year. You have really messed up this issue.
- 11(460) : Yet more garbage! Given what I have tried to explain above, it is ludicrous to consider daily data as part of the baseline climatology. The impacts variable may require daily data from a baseline period in order to define ITS reference level (but probably not), but this is NOT the same thing. Either all this is very badly worded, or you don't know what your doing.
- 11(468) : No!! Think about it!
- 11(470) : No!! This is NOT the reason.
- 11(473) : No!! Not 'observed' (which is past or present), but FUTURE data.
- 11(482-483) : Duplication.
- 12(to 492) : This is a very confused paragraph.
- 12(497-499) : Wrong. For upper air, there is a major paper by Santer et al. (JGR, 1999), which also touches on some surface issues. There are also a number of papers by Trenberth that are relevant.
- 12(507) : Again, introduction of an undefined term/concept (downscaling).
- 12(510) : At last, mention of changes. Sadly, it is inappropriate here, since this is NOT the reason.
- 12(514) : Why should this Figure be here?
- 12(518) : Wrong. As a scenario, this could be justified. You are confusing scenario (as you have defined it, which I have already criticized) with prediction/projection.
- 12(521) : See above.
- 12(525-527) : This is the Def. 1 vs Def. 2 issue. However, you have

the history and motivation wrong.

12(527-531) : Wrong. This issue has nothing to do with cold start vs warm start; it is to get over the drift problem (which it fails to do).

12(537) : Not 'especially'; mor appropriate may be 'but only'.

13(543) : 'were'; grammar!

13(543-545) : Not clear.

13(552-553) : Not clear.

13(579-581) : So what? Given your definition of scenario, this doesn't matter.

14(594) : Why use 'perceived'?

14(604) : This issue was first raised by Kim et al. (1987?).

It was first addressed in a credible manner by Wigley et al. (1990).

14(606) : 'appending' is a ridiculous word to use. Try 'adding'.

14(608) : 'often' to 'usually'.

14(613) : 'appended' to 'added'.

14(616) : 'appended' to 'added'.

14(617) : 'appended' to 'added'.

14(627,628) : Please cite the key initial papers by Kim et al. and Wigley et al.

15(635,636) : Clumsy sentence.

15(638) : Isn't the word 'physical' usually used? The process does not just involve dynamics.

15(642-648) : Mention of 1-way vs 2-way nesting needed here.

15(657-659) : You have failed to mention the most important reason for using LAMs, orography/topography.

16(667) : Please cite the key initial papers by Kim et al. and Wigley et al.

16(673) : 'predict and' to 'predictand'.

16(679-683) : Once again, you fail to mention the main advantage; viz. that statistical downscaling involve real-world data and so ensures that inter-variable relationships are realistic. Of course, these relationships may change; but LAMs don't even get the correct relationships for the present.

16(703)-17(716): These are VERY important results. They need far greater emphasis.

17(720) : In Australia? Or anywhere for that matter.

17(723-724) : See, e.g., Wigley (1999 - Pew report- and material cited therein).

17(725) : 'muiltple'?

17(730-732) : Not clear.

17(739-740) : This sentence sounds stupid. Rephrase.

- 17(744) : You cannot say 'most areas' and then cite only agriculture cases.
- 17(748) : The first clear exposition of this is in the oft-cited paper by Wigley (Nature, 1985). See also later paper in Climate Monitor.
- 17(755-756) : I disagree. Both methods have strengths and weaknesses.
- 18(770) : At last! A definition of 'weather generators'.
- 18(778-779) : Unclear.
- 18(798) : What means 'more definitive'?
- 18(803) : "Wilk's" to "Wilks".
- 18(805) : Hence, the work is irrelevant in the present context.
Delete irrelevant text.
- 19(to 821) : Most of the agriculture studies dealing with the effects of variability changes are flawed since they fail to separate the low-frequency effect of induced changes in winter soil moisture levels from the specific effect of within-growing-season variability changes.
- 19(826-839) : Since this should refer back to lines 823,824, this whole section amounts to a giant non sequitur.
- 20(880) : One could be much stronger than this. The use of high spatial resolution information is more than just 'warranted', it is absolutely essential. However, there is another approach that you have failed to mention at all. This is 'upscaling' of the impacts model. There is some relevant work on this in papers by Jarvis and McNaughton (and vice versa). Another related approach is the direct modelling of spatial patterns of agricultural yield (as in work by Wigley and Tu Qipu, which relates yield patterns to climate patterns). Presumably one could apply a similar approach to direct modelling of river flow. These approaches complement the rather boring direct approach of downscaling, and they may well circumvent some of its problems.
- 20(898) : Under this comes: model errors; sensitivity uncertainties; aerosol forcing uncertainties; lag uncertainties, regionalization versus global-mean uncertainties.
- 21(905) : lesser or greater than what??
- 21(916) : 'adequacy' is not the right word; hoe about 'appropriateness'?
- 21(928) : I disagree. Re-analysis data for precipitation are simply not good enough, and precipitation is the key variable in most impact areas. Also, in the regions where scenario data are most needed, real observational data are available. Re-analyses largely provide useful new data in regions where

data are not needed. The authors seem not to have thought this through.

- 21(to 931) : There are two papers by Wigley (conference proceedings, edited by Hanisch) which address the issue of the relative magnitudes of different sources of uncertainty in global-mean projections (emissions, aerosol forcing, carbon cycle, other trace gases, climate sensitivity). These papers are singularly relevant to this section.
- 21(939) : Actually, the range for total emissions is from 7.9 to 29.0GtC/yr. For fossil CO₂ emissions, the range is 6.5 to 28.8GtC/yr.
- 21(943) : Not just 'time-dependent evolution', but anything that has a specific time attached to it.
- 22(948) : The reference to Alcamo et al. here seems either perverse or ignorant. Recall that the topic is CLIMATE scenarios. In this context, MAGICC/SCENGEN is FAR better suited to exploring the consequences (right down the line) of emissions 'uncertainties'.
- 22(959-960) : MAGICC/SCENGEN already does this at the global-mean level. Furthermore, at least three O/AGCMs have fully embedded sulphur cycles already.
- 22(968) : 'specifications' is the wrong word. These things are NOT 'specified'.
- 22(970) : 'determine' to 'have'
- 22(972) : See also Wigley's Pew report (1999).
- 22(974-976) : Not straightforward? This really is utter garbage. In MAGICC/SCENGEN, this is extremely easy and straightforward.
- 22(985) : Ah ha! The 1-way/2-way nesting issue surfaces at last!
- 22(989-990) : See above.
- 23(999) : Actually, this issue was first raised in Santer et al. (1990). It has also been addressed in papers by Wigley and Palutikof (probably before anyone else).
- 23(1010-1011): The wording here is not quite right.
- 23(1022) : First done in Santer et al. (1990).
- 23(1030) : If one assumes stable patterns, which has been shown to be okay for the CO₂ component of change, then the SNR problem can be minimized by using changes over a long time interval.
- 23(1033) : This average response method was alluded to in Santer et al. (1990). It was first implemented in ESCAPE and later in MAGICC/SCENGEN. A good illustration of the method, including some relevant discussion of it, is given in the Wigley Pew report (1999). One of the critical aspects of this method (which is not even mentioned here!) is that the results

must be normalized by the global-mean temperature before averaging.

24(1040) : Is this the ACACIA program run out of NCAR? This program was established some years ago, and it would be extremely confusing if there were two programs with the same acronym.

24(1047) : Not 'a few', but many -- CMIP1.

24(1060) : 'rations' to 'ratios'.

24(1060-1062): Not clear.

24(1073) : What means 'non-standard forcing'? In my view, something like IS92a forcing would be 'standard', whereas 1% compound CO₂ is 'non-standard' (i.e., unrealistic and artificial).

24(1076-1078): Really? Why? I think this statement is wrong. There are a number of ways to determine SNR values from a single O/AGCM run. (Note the continuing confusing use of 'GCM', instead of O/AGCM.)

24(1085) : I don't think 'uncertainties' is quite the right word here. Input emissions scenarios, which are scenarios in the strict sense of the word, do not directly address uncertainty issues (although they can, with some trepidation and a not-inconsiderable amount of ingenuity, be used to define uncertainties). By the way, as far as I can see, the only scenario development method/software that does address the input and uncertainty issues is MAGICC/SCENGEN.

25(1090) : Again, these are not the most appropriate references. Key references are Santer et al. (1990), and papers on ESCAPE and MAGICC/SCENGEN.

25(1093) : What means 'annotation' here?

25(1102) : Actually, it was my idea.

25(1105,1106): No! The key assumption is actually linear superposition.

This is the way that SO₄ effects are handled. There are a number of papers that show that this assumption works well for temperature, and a paper by Ramaswamy and Chen in GRL that shows that it works also for precipitation. The tricky thing for this variable would be to prove statistically that it doesn't work. Given the SNR, it would be very difficult to reject the null hypothesis that $P(A)+P(B)=P(A+B)$, where A,B are the forcings and P(.) is the response pattern.

25(1108) : Plus numerous other papers.

25(1112,1113): This is very galling. The method may have been used in IMAGE, but they got it from ESCAPE, which goes back to Santer et al. (1990). MAGICC/SCENGEN pushes the idea as far as is possible. Schlesinger's COSMIC does things quite

similarly to MAGICC/SCENGEN. (Schlesinger was a co-author of the Santer et al. paper.)

25(1115) : Not clear.

25(1122) : All you can say here is 'may not hold', not 'probably does not hold'. Indeed, there are reasons to expect it to hold quite well.

25(1123) : Could begin new paragraph with 'Uncertainties'.

25(1123,1124): I think this statement is categorically wrong. MAGICC/SCENGEN incorporates SO₄ influences, as does COSMIC. There is no evidence at all that the uncertainties are thereby amplified. Indeed, there is evidence to the contrary (e.g. Penner et al., 1997). Idle and unsupported speculations like this do nobody any good.

25(1124,1125): I suspect your argument here would have to hinge on the possible spatial effects of a THC slowdown or shutdown. If so, say so. But, if this is the case, you must also note that the latest non-flux-corrected O/AGCMs do not show these major THC changes, and scaling approaches may well work out very well for these situations, even in stabilization cases. Please avoid jumping to unsubstantiated conclusions.

25(1125) : I refereed this paper, and I judged it to be an appalling display of ignorance. It should not be cited.

26(1134) : Why is this Figure here?

26(1138) : Ah ha! At last the normalization issue. This must come much earlier.

26(1144-1147): This is simply wrong. It is true that Ramaswamy and Chen dreamed up a case with big hemispheric-scale responses but little global-mean response, but this was totally unrealistic. In all cases that I have looked at, using the method employed by MAGICC/SCENGEN and COSMIC, this is simply NOT a problem.

26(1147,1148): Again, this is just WRONG!

26(1150+) : Again, this is my idea, and it was first implemented in MAGICC/SCENGEN. Please give credit where due.

26(1156-1159): Isn't this ALWAYS the case. In other words, the scaling method is almost universally applicable and useful.

26(1159-1162): I do not think this has been proven.

26(1164,1165): There are other methods, too.

26(1172) : Oh come on! Scaling handles MANY types of uncertainty (perhaps all), not just 'one type'.

27(1181) : 'documented' to 'quantified'?

27(to 1185) : etc., etc.

27(1193) : MAGICC/SCENGEN allows the user to consider this issue

by providing data on global precipitation pattern correlations.

Indeed, this software was the first to consider this issue (in spite of the Whetton and Pittock paper cited on line 1199).

27(1198-1201): Very clumsy text.

27(1203-1204): This is an issue we considered years ago in developing ESCAPE and MAGICC/SCENGEN. The trouble with judging a model on its regional performance is one of statistical significance.

It is much easier to get a good regional result by chance than to get results that are good globally.

27(1208-1211): Very clumsy text.

27(to 1214) : You have failed to mention a key issue. Is model skill in simulating present-day climate a reliable indicator of its skill in predicting future climate change? There is no evidence to support this idea, although it does sound a priori reasonable.

You must at least raise the issue.

28(1227) : Cite Morgan and Keith (1995) here.

28(1231) : This is a critical point. It needs more emphasis.

28(1235+) : What about inter-variable consistency? This needs to be discussed.

28(1236) : 'the manifold' to 'possible'.

28(1239) : Insert 'give' after 'chapters'.

28(1252) : Not clear.

28(1255) : So what? It is almost certainly irrelevant unless the CO₂ changes are bigger than anything anticipated, or unless there are nonlinear effects associated with THC changes (which looks increasingly unlikely).

28(1257) : 'mimics'? You must be joking! How about 'approximates'?

28(1262) : 'equal' (grammar).

28(1262,1263): How can smart people like this make such an elementary mistake!

29(1280,1281): This does not seem to be an appropriate reference.

29(1282) : 'albino' to 'albedo'.

29(1294) : This sea level consistency issue was first addressed by Wigley and Raper (Warrick et al. sea level book). It is, of course, avoided in MAGICC/SCENGEN.

29(1295) : 'dependable' to 'dependent'.

29(1295-1301): A giant red herring! Maybe some ignorant people produced inconsistent scenarios like this years ago, but the issue was also resolved years ago. All you need to say is that comprehensive software suites avoid these naive problems. Concentrate on the strengths of existing methods/software; don't reraise issues that were solved long ago.

29(1305-1308): Another misleading red herring, that fails to reflect

the current state of the science. Global-mean responses to aerosol forcing CAN be used to drive regional patterns. This is just what is done in MAGICC/SCENGEN and COSMIC.

29(1310,1311): Not clear.

29(1314) : Delete 'scenario'.

29(1318) : 'to daily' to 'in daily'.

30(1329,1330): 'stimulated new techniques' Oh yeah? The MAGICC/SCENGEN method has not changed in 7 years, and it still represents the state of the science.

30(1332,1333): True, but you have not explained them very well. Could you not have a summary Table that lists the strengths and weaknesses of the various methods, including the direct use of O/AGCM output. This would have helped you a lot in planning and structuring this chapter. It can still help in revising it; and be useful to readers.

30(1336-1339): Not clear.

30(1342) : You have mentioned this before, but you have failed to tell us what it is or given any example. A mention alone is valueless.

30(1344) : What means 'semi-formal'. I thought it was a dress protocol.

30(general) : A crucial need for scenarios (and for simple models) is to expand the range of cases covered by O/AGCMs.

Subject: Re: masking of WWF maps
Date: Thu Jul 29 09:13:24 1999

Jenny,

Thanks for these.

After entering into debate with Barrie Pittock, I have decided to shift to using the 1 sigma level as a mask for all maps. This will not affect any of the temperature plots you have done until now, but means that the China and C.America precipitation maps will need re-drawing using 1 sigma. Please let me know when these are done.

Note also for Russia and that everything from now on for WWF (both T and P) should use 1 sigma as the mask.

Sorry about this and I realise this squeezes even more time away from the RCM.

Given what has happened and your role in producing these plots, you may be interested in the exchanges I have had with Barrie Pittock - it illustrates nicely the nuances of presenting climate scenarios in different Fora. Read these three emails in reverse order.

Mike

Dear Mike,

Thank you for your careful consideration of my "trenchant comments". I am now much happier with what you are doing, and indeed grateful for your hard work and enterprise in getting the new scenarios out so quickly for both IPCC and WWF. Shifting to a one standard deviation is certainly an improvement, along with some discussion of possible changes in extremes. I fully appreciate that analysis of daily output is a time-consuming future task, but meantime an appropriate caveat is needed. Maybe an additional upfront paragraph discussion of the very issues we have discussed re providing best estimates of changes, even if their statistical detectability can only be established after a long time period has elapsed, would be useful?

I should perhaps explain my delicate position in all this. As a retired CSIRO person I have somewhat more independence than before, and perhaps a reduced sense of vested interest in CSIRO, but I am still closely in touch and supportive of what CAR is doing. Also, I have a son who is now a leading staff member of WWF in Australia and who is naturally well informed on climate change issues. Moreover, Michael Rae, who is their local climate change staffer, is a member of the CSIRO sector advisory committee (along with some industry people as well) and well known to me. So I anticipated questions from WWF Australia, and from the media later when the scenarios are released, regarding the scenarios. I did

not want to be in the position of feeling the need to seriously question in public their presentation or interpretation. You have allayed my fears on that score, so that is great.

Roger may still follow up with some more detailed comments he is collating from people in CAR.

Best regards,

Barrie.

Barrie,

Thanks for your trenchant comments re. the scenario maps.

Let's get the bit about extremes out of the way because in what WWF have asked us to do (or what Tim Carter and I have done for WGII) we cannot produce new detailed analyses for all the 15 regions we are doing of GCM-based changes in daily or sub-daily events. Clearly for (some, many?) impacts such changes will be important and we (do and will) make comments to this effect in various places. [By the way, we do show some analyses of changes in the probability of extreme *seasons*, if not extreme days].

Your main point of contention, however, is about the portrayal of changes in mean seasonal T and P (and we are talking about 30-year climate averages here).

My reason for introducing the idea of only showing changes in T and P that *exceed* some level of 'natural' variability was a pedagogic one, rather than a formal statistical one (I concede that using '95% confidence' terminology in the WWF leaflet is misleading and will drop this). And the pedagogic role of this type of visual display is to bring home to people that (some, much or all of) GCM simulated changes in mean seasonal precip. for some regions do *not* amount to anything very large in relation to what may happen in the future to precip. anyway - a classic example is the African Sahel where *none* of the GCMs get precip. changes anything like as large as have been seen this century.

The reasons for this may be 1) because the GHG signal is poorly defined, i.e., a scatter of GCM P changes both above and below zero, and/or 2) because even with a tighter bunching of GCM predictions in one direction these may still not be large relative to 'natural' variations in 30-year mean precip. My approach of taking a pseudo-ensemble of GCMs, standardising and scaling and then plotting the Median *in relation to* natural variations is I think one of the more elegant ways of showing this. Of course, we could define natural variability to be the 1 sigma rather than the 2 sigma level, or simply the interquartile range of control climates or even just the 40-60 percentile range. What one chooses is a matter of judgement and probably for WWF I should use a less extreme threshold than 2 sigma.

The point behind all this is to emphasise that precip. changes are less well-defined than temp. changes *and* that we should be thinking of adaptation to *present* levels of precip. variability, rather than getting hung up on the problems of predicting future precip. levels. This pedagogic thinking is hard to communicate in a short WWF brochure.

Your concern about my message is well taken, however, and I intend to remove any reference to 95% confidence levels, to re-word the text to indicate that we are plotting precip. changes only 'where they are large relative to natural variability', and to reduce my threshold to the 1 sigma level of HadCM2 control variability (e.g. this has the effect of showing precip. changes for the majority of Australia even in the B1 scenario).

But I do not intend to abandon the concept. I think it important - even for Greenie groups - to present sober assessments of magnitudes of change. Thus making it clear that future changes in T are better defined than future changes in P, and also to point out that future emissions (and therefore climate change) may be as low as the B1 scenario (is B1 climate change negligible? I almost think so), whilst also being possibly as high as A2 is I think very important.

The alternative is to think that such a more subtle presentation is too sophisticated for WWF. But I think (hope) not.

Thanks again Barrie for forcing me to think through this again.

Mike

Hi Mike,

I'm sure you will get some comments direct from Mike Rae in WWF Australia, but I wanted to pass on the gist of what they've said to me so far.

They are worried that this may present a slightly more conservative approach to the risks than they are hearing from CSIRO. In particular, they would like to see the section on variability and extreme events beefed up if possible. They regard an increased likelihood of even 50% of drought or extreme weather as a significant risk. Drought is also a particularly important issue for Australia, as are tropical storms.

I guess the bottom line is that if they are going to go with a big public splash on this they need something that will get good support from CSIRO scientists (who will certainly be asked to comment by the press). One paper they referred me to, which you probably know well is: "The Question of Significance" by Barrie in Nature Vol 397, 25 Feb 1999, p 657

Let me know what you think. Adam

Dear Tom,

Thanks for bringing that to our attention...

I checked out that page and, unfortunately what he has done is *so* ridden with problems that it isn't even worth confronting. Many of us (e.g., me, Phil Jones, Henry Pollack, Shao-Yang Huang, Rob Harris, and others) have been scratching our heads trying to find a statistically defensible way of combining the information in boreholes and "conventional" proxy indicators, and as yet it is not clear if it can be done, given in particular the loss of information due to geothermal diffusion, and the overriding important of land-usage changes and snowcover variations, on borehole temperature profiles. I don't think Hoyt has added anything scientifically productive in this regard. Looks more like he has wrecklessly convoluted borhole data with our reconstructions to get just the kind of result he wants to get...

Of course, there are issues with regard to secular trends in dendroclimatic reconstructions (which form an important, but not exclusive, role in our reconstructions) and nobody is better qualified to discuss these than Keith, or Malcolm Hughes, who have highlighted these issues in recent publications (there is a link to a nice recent "Nota Bene" Science piece by Keith and Tim Osborn on my webpage:

<http://eclogite.geo.umass.edu/climate/mike/mbh99.html>

With regard to "Co2 fertilization", it is ironic that Hoyt frames his analysis in these terms, when it precisely this effect (for better or for worse) we took great pains to account for in our recent millennial temperature reconstruction (see the above web page for more info). At least, we have done this in a reasonably statistically-defensible, if imperfect, manner, rather than an ad hoc attempt to get an answer, rather than follow

a scientifically meaningful process.

This thing wouldn't have a chance at passing peer-review (at least, not on this planet), so he posts it on the web--the downside of absolute freedom of dissemination I suppose. The material in question is the scientific equivalent of trash, plain and simple.

Like a lot of the "skeptics" out there, D.H. appears far less interested in honest scientific discourse, than in misleading as many unlucky soles as possible who wander into his den of disinformation (kind of like the "scientist" equivalent of an Ant Lion I suppose).

Every once and a while, I do choose to respond to this type of crap (e.g., with regard to Pat Michaels--my soon-to-be "neighbor"'s recent pieces in his "World Climate Report"). In D.H.'s case, I doubt even more that this would be at all productive. We just have to wait and see if he ever tries to get this kind of thing published in the peer-reviewed literature. For our part, I think the best approach is to, as Jonathan Overpeck has so effectively been doing, try whenever possible to educate the lay public about the essential distinction between peer-reviewed science and un-peer-reviewed...., well, whatever you want to call it.

Again, thanks for the head's up on this.

best regards,

mike mann

Mike,

I thought maybe I could contribute a few comments to your concern over using a common coverage mask for surface and MSU temperatures. (Copy of your relevant paragraph copied below.)

Whether or not to mask depends on the question being addressed. If we wanted the best estimate of global mean MSU temperatures, then clearly we wouldn't want to mask. The issues we address, however, are largely based on an expectation (from models and observations) that over large portions of the globe strong vertical coupling tends to lead to large positive correlations between surface and lower tropospheric temperatures. There is a further (model-based) expectation that any warming trend at the surface should be slightly amplified higher up in the troposphere. These expectations seem to be contradicted by the MSU data (at least for global mean trends).

Masking makes most sense if there is in fact strong coupling between the surface and troposphere. Suppose the CO₂ warming signal were one with relatively strong warming over land areas and weaker warming over ocean. Suppose further that we only had surface temperature measurements over land, but had MSU retrievals over all the globe. Also assume a case of perfect coupling (1K rise in local upper air temperature for every 1K rise in local surface temperature).

In this case the unmasked global mean MSU temperature increase would be less than the "global" mean surface temperature increase, falsely indicating a damping with height of the CO₂ signal. If we masked the MSU temperature (sampling only over land), then the global means would be computed over the same area as the surface temperature and the MSU temperature change would equal the surface temperature change, indicating no damping of the response with height. This second conclusion would be the correct one. Note, however, that the true global mean temperature change (both at the surface and

aloft) would be best estimated using the MSU unmasked data (under the conditions of this hypothesized case).

Under different conditions, and again depending on what question is being addressed, it might be best not to mask the MSU data. In our paper we wanted to determine whether the apparent discrepancy between the MSU trend (very small) and the surface trend (positive, and larger) could be explained by coverage differences. This makes sense since models seem to indicate that the trends should be comparable. One explanation for the discrepancy is that in models true global means had been considered until now, whereas in the data the MSU mean was computed from global coverage, but the surface changes were computed from data covering about 70% of the globe. In our study both model data and observations were treated with the same mask so we rule out different sampling as a full explanation for the difference between surface and MSU temperature trends.

Hope this doesn't confuse things further.

cheers,
Karl

Mike wrote (in part):

I think one needs to be very careful about this coverage argument--basically because the atmosphere can move anomalies around compared to the surface. One would just not expect their spatial patterns to be the same, so taking a common spatial mask will not resolve this (even if it seems plausible). To illustrate, take an extreme example of there only being sfc msmts for the equatorial eastern Pacific (the El Nino region). There, the MSU and sfc temp go in opposite directions for quite plausible physical reasons. Doing a mask and comparing for that small region would make no sense and give negative correlations, etc. Now, in that sfc obs cover most of the globe, the problem will not be so severe, but it persists (it was for this reason that I was suggesting extrapolating to the global value for sfc temp based on changing coverage--not sure how to do that however). In any case, I believe that MSU and sfc should only be compared, if at all, for the globe as a whole.

Subject: Proposal to IARC
Date: Mon, 6 Sep 1999 17:18:44 +0500
Reply-to: "Stepan G. Shiyatov" <stepan@ipae.uran.ru>

Dear Keith,

Some days ago we have got "JOINT ANNOUNCEMENT OF OPPORTUNITY" from International Arctic Research Center and Cooperative Institute for Arctic Research University of Alaska Fairbanks. The general theme is Global Change Research in the Arctic (full text with description is attached bellow). As we have read Research Themes from announcement they seem to be very congenial to our laboratory. What do you think about this? Is there point in submitting proposal to IARC and CIFAR at the University of Alaska Fairbanks? Research theme would be 5,000 year summer air temperature reconstruction from tree rings and impacts and consequences of global climate change on forest ecosystems in the Polar Ural and Yamal Peninsula (Subarctic regions of Russia).

We have no wide experience to submit proposal to any foreign administration. We need in some advice. Could you give us a piece of good advice how to do this well.

The questions are:

1. We are not sure whether this action and theme is contrary to our future cooperative work?
2. If not, how big our chance to get award?
3. Could we submit a proposal from our Institute only without U.S. partner? (Proposals from foreign institutions should preferably have a U.S. partner. See description bellow). If U.S. partner should be, who in your opinion would be?

Best regards.

Stepan.

Arctic Research University of Alaska Fairbanks
Global Change Research in the Arctic

INTRODUCTION

Proposals are invited on topics of global change and its effects in the Arctic (detection; interactions and feedbacks; paleoclimates, arctic haze, ozone and UV; contaminants; impacts and consequences of change). The proposal deadline is 1 October 1999 and awards will be made in January 2000.

DESCRIPTION

The International Arctic Research Center (IARC) and the Cooperative Institute for Arctic Research (CIFAR) at the University of Alaska Fairbanks announce the availability of funding for global change research in the Arctic. The IARC is a new international research center at the University of Alaska Fairbanks, established jointly with Japan. The mission of the IARC is to provide an environment that will nurture multidisciplinary research by integrating and synthesizing past, present, and future studies in global change.

CIFAR is the NOAA-UAF Cooperative Institute for Arctic Research; it is combining the resources of its Arctic Research Initiative (ARI) with those of IARC under this announcement. The goal is to develop a focal point for a pan-Arctic synthesis of global change in which researchers from many different institutions throughout the United States and the rest of the world participate to combine their research results. Further details on IARC can be found on its web page at <http://www.iarc.uaf.edu/> and on CIFAR at <http://www.cifar.uaf.edu/>.

Proposals may be submitted from U.S. or foreign institutions that address studies on any of the following themes drawn from the IARC Science Plan and the CIFAR Arctic Research Initiative. Proposals from foreign institutions should preferably have a U.S. partner. The starting date for proposed work should be 1 January 2000, with a duration of up to 24 months. Funding for the second year will be contingent on the availability of additional funds, therefore each proposal should have a clear, achievable objective for the first year's work.

RESEARCH THEMES

1. Detection of contemporary climate change in the Arctic by ground observations, remote sensing and climate "fingerprinting".
2. Arctic paleoclimatic reconstructions from ice cores, tree rings, permafrost, lake and ocean sediments.
3. Atmosphere-ice-land-ocean interactions and feedbacks in the Arctic that affect change, including observations and modeling.
4. Arctic atmospheric chemistry, arctic haze, ozone and UV radiation and their effects.
5. Impacts and consequences of global climate change, including effects on biota and ecosystems in the Arctic.
6. Contaminant sources, transport pathways, and exposure to higher trophic levels and humans in the Arctic.

It is planned to fund several large projects and a number of medium (\$100K) or smaller projects. Proposals must include the full cost of logistics support required. A total of about \$ 4.5M is available in year 1 for this Announcement of Opportunity.

Proposals can request support for the following:

- * Research on any of the above six themes. Proposals that add value to ongoing research projects, or that share costs with other funded investigators, are encouraged.
- * Conducting workshops at the IARC to further define priorities or synthesize available information on any of the research themes listed above, or any theme from the IARC Science Plan.
- * Visiting scientists, for short- or longer-term visits, to the IARC in Fairbanks.
- * Development of generally useful curricula and courses in global change, or conducting global change outreach and educational activities.
- * U.S. participation in the work of the Arctic Council and its AMAP, CAFF, or PAME working groups.

All proposers should meet the following conditions:

- * PIs must attend an annual synthesis meeting of all IARC/CIFAR investigators in Fairbanks at which research results will be presented and working groups will synthesize results. Proposal budgets should include travel to Fairbanks.

- * All activities will be required to acknowledge the financial support from IARC and CIFAR in reports, papers, dissertations, etc.
- * Progress reports are due from all funded projects on 1 August 2000.
- * Copies of all publications resulting from funded projects are to be provided to IARC/CIFAR.

Proposals should not exceed 15 pages in text and illustrations, not counting CVs, budget page, and appendices. Further details on proposal preparation are attached below as an appendix.

Review criteria for research proposals are:

- * Does the proposal address the research themes listed above?
- * Does it propose high-quality research?
- * Does it advance the NOAA mission?
- * Is the PI (or are the PIs) well qualified to do the research?
- * Can the research be done in a timely manner?
- * Is it likely to lead to significant results?
- * Is it likely to contribute to a synthesis of research results on global change?

Proposals must be received by 1 October 1999. All proposals will be reviewed by a scientific peer review panel of prominent researchers that will advise a program management team drawn from NOAA, IARC, and CIFAR. Funds will be available in early 2000. Please submit proposals (originals and 10 copies) to the address below. Further information can also be obtained from the same office.

Gunter Weller, Director, CIFAR, University of Alaska, Fairbanks, AK

APPENDIX

INSTRUCTIONS FOR PROPOSAL PREPARATION FORMAT OF THE PROPOSAL

Proposals should be stapled in the upper left-hand corner, but otherwise be unbound, and have 2.5-cm margins at the top, bottom, and on each side. The type size must be clear and readily legible, in a standard font size of 10-12 point. The original signed copy should be clipped together (not stapled) and printed on one side of each sheet only. The 10 additional copies of the proposal may be printed on both sides.

When submitting collaborative proposals involving more than one institution, each institution should submit its own cover page with appropriate signatures and its own budget. The title of the proposal, the text, disclosures, vitae, etc., should be the same and a cover letter should indicate that the proposal is a collaborative one jointly submitted with another (or other) institution(s) which should be named.

SECTIONS OF THE PROPOSAL

1. Cover page. The cover page should include a title, the Principal Investigator's name(s) and affiliation(s), complete address, phone, fax, e-mail information, and budget summary broken out by year. It must be signed by an official authorized to legally bind the submitting organization.
2. Half-page abstract (on a separate page). This should list the nature of the proposed work (e.g., hypotheses to be tested, the relationship of the proposed studies to the research themes, the goals of any proposed workshops, relationship to the Arctic Council, etc.) and a summary of the key approach.
3. Project Description. This section should present the problem or opportunity to be addressed by the project, and state the questions, hypotheses, and project objectives, clearly relating them to the goals of this competition. Proposals should: summarize the approach that will be used to address the questions, hypotheses, and objectives; describe how the PIs and co-PIs would contribute to the overall study approach; describe the methods to be used; and present expected results.
4. Data Plan. The proposal should include a plan on

how the data generated by the proposed research will be made available to other scientists (e.g., web pages) and deposited in a recognized data archive.

5. References cited.

6. Milestone chart for the project.

7. Statement of the project responsibilities of each Principal Investigator and participant.

8. Budget. Pattern your budget after NSF

budget Form 1030. Budget categories include the following: salaries and wages, fringe benefits, equipment, travel, materials and supplies (expendable), publication costs, consultant services, computer services, sub-awards, tuition, other expenditures, and indirect costs (facilities and administration). The full cost of logistics should be included in the budget. Travel to an annual PI meeting in Fairbanks should be included. Travel expenses need to be broken down by airfare and per diem. Salaries for Government PIs will not be supported.

9. Biographical Sketch. This is limited to two pages for each Principal Investigator and should be focused on information directly relevant to undertaking the proposed research.

10. A short list of possible peer reviewers with whom you have no close working or personal relationship (optional).

11. Federal employees. Proposals are welcome from those Federal agencies whose legislated mission allows participation.

NONDISCRIMINATION The National Oceanic and Atmospheric Administration provides awards for research in the sciences. The awardee is wholly responsible for the conduct of such research and preparation of the results for publication. NOAA, therefore, does not assume responsibility for such findings or their interpretation. IARC and CIFAR welcome proposals on behalf of all qualified scientists and engineers, and strongly encourage women, minorities, and persons with disabilities to compete fully in any of the research and research-related programs described in this document. In accordance with Federal statutes and regulations, and NOAA policies, no person on the grounds of race, color, age, sex, national origin, or disability shall be excluded from participation in, denied the benefits of, or be subjected to discrimination under any program or activity receiving financial assistance from NOAA.

Stepan

I have just returned from a week at a PAGES meeting in Switzerland. I presented the Yamal and Taimyr chronologies along with our recent analyses of the spatial patterns of variability in the northern network and the pressure and temperature interpretation of the patterns. All of this was well received.

As for your questions, it is very short notice to consider getting a well organised proposal together. My answers to your specific questions are
1. Such work would not necessarily be contrary to our current and future plans but there is undoubtedly a potential overlap and possible problem in distinguishing tasks and outputs. The next EC proposal must be clearly separate and I would be concerned if the potential referees asked what was the clear difference.

2. I have no experience (and presumably neither has anyone else as this is a new initiative) but I think the chances would depend on the degree of synthesis involved in the work and possibly how extensive the overall scope of the work is and also maybe who the U.S. collaborator is. I think your chance would be better as part of a large project , somewhat as we envisage for the next EC application. This is my opinion only and it may , of course, be wrong.

3. I see nothing preventing an application from your laboratory alone . If you do put in an application I would hope it made clear our ongoing collaboration. If you went for a collaborator in the U.S. the obvious person is Gordon Jacoby. I do not know if he is already submitting but I would think so. Please let me know what you decide . I will be phoning Gordon anyway to ask him about future collaboration on the EC front. I will keep you informed on that.

very best wishes

Keith

Subject: Proposal to IARC
Date: Wed, 8 Sep 1999 16:44:52 +0500
Reply-to: "Stepan G. Shiyatov" <stepan@ipae.uran.ru>

Dear Keith,

Thank you for answers to my questions. We decided do not participate in this project, as many problems are originated. And there is no time to write such proposal.

Last week I came back from the Polar Urals. The fieldwork was successful this summer. We remeasured all trees and seedlings along the transect, mapped forest-tundra ecosystems and tree-line over a large territory, made about 100 photos. I found very old living twigs of *Juniperus sibirica* (up to 700-800 years) and took samples from many dead twigs. We also collected many wood samples from living and dead larches of various ages. But we were bited by many thousands of mosquitos especially small ones.

Sincerely yours,

Dr. Stepan G. Shiyatov

Subject: Discussion document for Tues/Wed

Date: Sun, 12 Sep 1999 12:21:08 +0100

Attached is a discussion document. It incorporates material provided by Simon Shackley (UMIST) & Mike Hulme. Jean has commented on it. It is intended to circulate this to consortium partners on Monday. if you have chance to read it & comment on it before it goes, that would be good; but I recognise that - in practice - time is too short. My apologies for that. (However, I do think there is a danger in presenting our partners with too 'final' a draft application at this stage. And we do need their bright ideas!).

CHRIS - please will you liaise with Jean to:

1. Get this document out to outside attendees.
2. Send out a list of attendees
3. Give outside people details of where to get the Research Councils' document 'Information for applicants to run the Centre' (web), if they don't already have it.
4. Send out an agenda (Jean is doing this)
5. Send out Kerry's diagram (Jean has)

CHRIS - will you also please fax copies of the ICER document (in your tray) to John Shepherd (Southampton 596258) and Nigel Arnell (I don't have fax number). [For info to others - we didn't send Soton a copy of the ICER bid earlier, because they were sitting on the fence].

Very many thanks.

Trevor

CONFIDENTIAL TO ENV - State of Play

The research councils want a 5000 word outline bid by mid-October. The councils are putting up 2 million pounds per year for 5 years are NERC, EPSRC and ESRC. The research councils are putting the emphasis on "solutions" to climate change. They are clearly not looking for another version of CRU, the Hadley Centre, or any other existing centre in the UK. The focus is "downstream" of these existing centres.

Much of what they appear to want we anticipated in our JIF ICER (Institute for Connective Environmental Sciences) bid and, indeed, we made a provisional early strike for the CCC in that bid, although the research councils' intentions were not known at that point. Even if the JIF ICER bid is unsuccessful (& at this stage we are still optimistic), then we will still be able to take advantage of this "early" thinking in the final CCC bid.

We are aware of 3-4 competitors, which are mainly consortia of some form. Our consortium includes UMIST (number of departments), Southampton (number of departments), Cambridge (Dept of Econometrics), Sussex (Science Policy Research Unit), Cranfield (Ecotechnology Unit- Complex Systems Modelling), and Leeds (Institute for Transport Studies). There will also be a number of institutes associated with us, including Inst. Hydrology, BAS, Inst.

Terrestrial Ecology, Rutherford Appleton Laboratory, Building Research Establishment, John Innes Centre, and possibly other Institutes such as the Plymouth Marine Lab & the Proudman Oceanographic Lab. The hub of this consortium will be UEA. Visiting fellows etc will work in the Centre (& possibly also at 'secondary' centres like UMIST).

Business/industry links are important, as are links with relevant institutes abroad. We anticipate writing in some industrial/business partners.

Our philosophy is not to seek to maximise the input of resources to UEA, or to the consortium, in the short term, but to build a Centre which has the credibility and the authority to identify, initiate, orchestrate research programmes, and to include the best people available. We see this as the likeliest way to attract long-term funding & to ensure the long-term future of the CCC.

We have a fairly clear idea of the "science framework" of the CCC and, together with our partners, are now agreeing the "research challenges". At the moment the research challenges look something like this:

1. DEVELOPING THE TOOLKIT

Given that the Centre's starting point is to take advantage of the best research internationally (extant, on-going, and planned), it will be necessary to apply, refine, and develop methods of 'integration'. Much science and engineering research is focused on specific disciplinary issues. This has to be brought together with critical analyses of social and economic factors, to design more adaptive and effective policies, and more effective and appropriate engineering/technology. The best aspects of 'integrated assessments' will be applied with a UK focus. An important part of such assessments will be isolate emerging opportunities (for business/industry) afforded by climate change - in order to identify competitive opportunities it will be necessary to consider global pressure points. Existing models need to be linked. Reduced complexity modelling has a significant role.

The Toolkit can also be developed and tested via geographically-focused studies. For example, integrated coastal (incl. estuaries) management which will include: risk analysis; valuation of coastal environments; effects of adaptation (soft/hard engineering solutions) on coastline; ecological/economic models; etc.

Methods to characterise/measure vulnerability and adaptive capacity.

The Toolkit will also include some of the consultation/inclusion techniques outlined in UEA's JIF bid for ICER.

2. ABRUPT CHANGES AND EXTREMES

'Climate' research on abrupt/non-linear changes (in 'underlying' climate) and on changes in extreme event frequency (some of the Tools will need to be applied - or adapted for - this Challenge: for example, vulnerability/adaptation, risk analysis, reduced complexity modelling). Of particular importance is how the possibility of abrupt/non-linear change should be assimilated into decision-making frameworks (perception/risk analyses, etc.).

It will be necessary to consider the implications of non-climate 'shocks' - political and economic shocks; or combinations, for example, climate/weather extremes influencing perceptions (amongst business community and politicians) leading to sudden shifts of policy, investments, etc.

3 CARBON MANAGEMENT AND TECHNOLOGY

Adoption of clean technology (includes 'alternative' energy sources, and removal of C from emissions). In particular, clean technologies and solutions for developing countries link into identifying business opportunities. The impacts of clean technologies - landscape/lifestyle valuation. Incorporation (technological) into existing infrastructure/supply networks.

a. Carbon 'sequestration' - options, waste C recycling, use in building materials, long-term storage, etc. Oceans. Ambitious bio-engineering? (discussions with Norwich's John Innes Centre on-going).

b. Energy efficiency (technological), including control systems, especially when concentrated on one of the scale 'foci' (e.g. the household).

4. MANAGEMENT OF SOCIAL AND TECHNOLOGICAL CHANGE.

Factor 4 and beyond 1. We will need to go well beyond Factor 4 to stabilise the climate system. This programme would analyse and assess different emission trajectories, and look at how we would in practice achieve Factor

4+. It would include assessment of tools such as: C trading, domestic tradeable carbon quotas, regulation and taxation, voluntary agreements, opportunities for win-win scenarios through resource use minimisation, etc. Also, it would look at changes to a low-C economy at different scales: households, SMEs, large firms, MNCs; local to regional to national to global, etc., to sectoral: transport, energy supply, heavy & light manufacturing, services & finance, etc. Technology uptake. This includes reducing transport emissions and exploring low-consumption (water, energy, carbon) households. What about air traffic?

The research challenges above are not intended to be all-inclusive. We intend to use Research Challenges such as these 4, as "exemplars" of the sort of thing we will expand upon in the final bid.

The research councils have emphasised the importance of attracting a top-rate international scientist as Research Director. They also wish us to name the Executive Director at this point. We believe it should be someone with a reputation in climate research in their own right, good links etc with the "impacts" people and with funders, as well as being a good manager/organiser. We anticipate naming Mike Hulme. From what we have heard, that will give us an additional advantage over other bids.

At this point, we will welcome your comment, input, suggestions.

Trevor

Thanks for your response Keith,

For all:

Walked into this hornet's nest this morning! Keith and Phil have both raised some very good points. And I should point out that Chris, through no fault of his own, but probably through ME not conveying my thoughts very clearly to the others, definitely overstates any singular confidence I have in my own (Mann et al) series. I believe strongly that the strength in our discussion will be the fact that certain key features of past climate estimates are robust among a number of quasi-independent and truly independent estimates, each of which is not without its own limitations and potential biases. And I certainly don't want to abuse my lead authorship by advocating my own work.

I am perfectly amenable to keeping Keith's series in the plot, and can ask Ian Macadam (Chris?) to add it to the plot he has been preparing (nobody liked my own color/plotting conventions so I've given up doing this myself). The key thing is making sure the series are vertically aligned in a reasonable way. I had been using the entire 20th century, but in the case of Keith's, we need to align the first half of the 20th century w/ the corresponding mean values of the other series, due to the late 20th century decline.

So if Chris and Tom (?) are ok with this, I would be happy to add Keith's series. That having been said, it does raise a conundrum: We demonstrate (through comparing an extratropical averaging of our northern hemisphere patterns with Phil's more extratropical series) that the major discrepancies between Phil's and our series can be explained in terms of spatial sampling/latitudinal emphasis (seasonality seems to be secondary here, but probably explains much of the residual differences). But that explanation certainly can't rectify why Keith's series, which has similar seasonality *and* latitudinal emphasis to Phil's series, differs in large part in exactly the opposite direction that Phil's does from ours. This is the problem we all picked up on (everyone in the room at IPCC was in agreement that this was a problem and a potential distraction/detraction from the reasonably consensus viewpoint we'd like to show w/ the Jones et al and Mann et al series.

So, if we show Keith's series in this plot, we have to comment that

"something else" is responsible for the discrepancies in this case. Perhaps Keith can help us out a bit by explaining the processing that went into the series and the potential factors that might lead to it being "warmer" than the Jones et al and Mann et al series?? We would need to put in a few words in this regard. Otherwise, the skeptics have an field day casting doubt on our ability to understand the factors that influence these estimates and, thus, can undermine faith in the paleoestimates. I don't think that doubt is scientifically justified, and I'd hate to be the one to have to give it fodder!

The recent Crowley and Lowery multiproxy estimate is an important additional piece of information which I have indeed incorporated into the revised draft.

Tom actually estimates the same mean warming since the 17th century in his reconstruction, that we estimate in ours, so it is an added piece of information that Phil and I are probably in the ballpark (Tom has used a somewhat independent set of high and low-resolution proxy data and a very basic compositing methodology, similar to Bradley and Jones, so there is some independent new information in this estimate.

One other key result with respect to our own work is from a paper in the press in "Earth Interactions". An unofficial version is available here:

http://www.ngdc.noaa.gov/paleo/ei/ei_cover.html

The key point we emphasize in this paper is that the low-frequency variability in our hemispheric temperature reconstruction is basically the same if we don't use any dendroclimatic indicators at all (though we certainly resolve less variance, can't get a skillful reconstruction as far back, and there are notable discrepancies at the decadal and interannual timescales). I believe I need to add a sentence to the current discussion on this point, since there is an unsubstantiated knee-jerk belief that our low-frequency variability is suppressed by the use of tree ring data.

We have shown that this is not the case: (see here:

http://www.ngdc.noaa.gov/paleo/ei/ei_datarev.html

and specifically, the plot and discussion here:

http://www.ngdc.noaa.gov/paleo/ei/ei_nodendro.html

Ironically, you'll note that there is more low-frequency variability when the tree ring data *are* used, then when only other proxy and historical/instrumental data are used!

SO I think we're in the position to say/resolve somewhat more than, frankly, than Keith does, about the temperature history of the past millennium. And the issues I've spelled out all have to be dealt with in the chapter.

One last point: We will (like it or not) have SUBSTANTIAL opportunity/requirement to revise much of this discussion after review, so we don't have to resolve everything now. Just the big picture and the important details...

I'm sure we can can up with an arrangement that is amenable to all, and I'm looking forward to hearing back from Keith, Phil, and Chris in particular about the above, so we can quickly move towards finalizing a first draft.

Looking forward to hearing back w/ comments,

mike

Mike,

Been away in Japan the last week or so. Malcolm was there in a wheelchair because of his ruptured achilles. We both mentioned the lack of evidence for global scale change related to the MWE and LIA, but all the later Japanese speakers kept saying the same old things.

As for the TAR Chap 2 it seems somewhat arbitrary divison to exclude the tree-ring only reconstructions. Keith's reconstruction is of a different character to other tree-ring work as it is as 'hemispheric in scale' as possible so is unlike any other tree-ring related work that is reported upon.

If we go as is suggested then there would be two diagrams - one simpler one with just Mann et al and Jones et al and in another section Briffa et al. This might make it somewhat awkward for the reader trying to put them into context.

The most important bit of the proxy section is the general discussion of 'Was there an MWE and a LIA' drawing all the strands together. Keith and I would be happy to look through any revisions of the section if there is time.

One other thing, did you bring up the possibility of having a proxy-only chapter (albeit short) for the next assessment ?

On Venice I suggested to Peck that you and Keith give talks on the reconstructions - frank and honest etc emphasising issues and I lead a discussion with you both and the rest of those there where the issues can be addressed (ie I would like to get the views of other proxy types and the modellers/detectors there). I suggested to Peck that this was early in the week as I have to leave on the Thursday to go to the last day of a Working Group meeting of the Climate Change Detection group in Geneva (a joint WMO Commission for Climatology/CLIVAR). I hope to report on the main findings of the Venice meeting.

Another issue I would like to raise is availability of all the series you use in your reconstructions. That old chestnut again !

How is life in Charlottesville ? Do you ever bump into Michaels or is always off giving skeptical talks ?

Tim Osborn is making great progress with his NERC grant and will be looking into dates soon for coming to see you.

Cheers
Phil

Hi everyone

Let me say that I don't mind what you put in the policy makers summary if there is a general concensus. However some general discussion would be valuable . First , like Phil , I think that the supposed separation of the tree-ring reconstruction from the others on the grounds that it is not a true "multi-proxy" series is hard to justify. What is true is that these particular tree-ring data best represent SUMMER temperatures mostly at the northern boreal forest regions. By virtue of this , they also definately share significant variance with Northern Hemisphere land and land and marine ANNUAL temperatures - but at decadal and multidecadal timescales - simply by virtue of the fact that these series correlated with the former at these timescales. The multi proxy series (Mann et al . Jones et al) supposedly represent annual and summer seasons respectively, and both contain large proportions of tree-ring input. The latest tree-ring density curve (i.e. our data that have been processed to retain low frequency information) shows more similarity to the other two series- as do a number of other lower resolution data (Bradley et al, Peck et al ., and new Crowley series - see our recent Science piece) whether this represents 'TRUTH' however is a difficult problem. I know Mike thinks his series is the 'best' and he might be right - but he may also be too dismissive of other data and possibly over confident in his (or should I say his use of other's). After all, the early (pre-instrumental) data are much less reliable as indicators of global temperature than is apparent in modern calibrations that include them and when we don't know the precise role of particular proxies in the earlier portions of reconstruction it remains problematic to assign genuine confidence limits at multidecadal and longer timescales. I still contend that multiple regression against the recent very trendy global mean series is potentially dangerous. You could calibrate the proxies to any number of seasons , regardless of their true optimum response . Not for a moment am I saying that the tree-ring , or any other proxy data, are better than Mike's series - indeed I am saying that the various reconstructions are not independent but that they likely contribute more information about reality together than they do alone. I do believe , that it should not be taken as read that Mike's series (or Jone's et al. for that matter) is THE CORRECT ONE. I prefer a Figure that shows a multitude of reconstructions (e.g similar to that in my Science piece). Incidentally, arguing that any particular series is probably better on the basis of what we now about glaciers or solar output is flaky indeed. Glacier mass balance is driven by the difference mainly in winter accumulation and summer ablation , filtered in a complex non-linear way to give variously lagged tongue advance/retreat .Simple inference on the precidence of modern day snout positions does not translate easily into absolute (or relative) temperature levels now or in the past. Similarly, I don't see that we are able to substantiate the veracity of different

temperature reconstructions through reference to Solar forcing theories without making assumptions on the effectiveness of (seasonally specific) long-term insolation changes in different parts of the globe and the contribution of solar forcing to the observed 20th century warming .

There is still a potential problem with non-linear responses in the very recent period of some biological proxies (or perhaps a fertilisation through high CO2 or nitrate input) . I know there is pressure to present a nice tidy story as regards 'apparent unprecedented warming in a thousand years or more in the proxy data' but in reality the situation is not quite so simple. We don't have a lot of proxies that come right up to date and those that do (at least a significant number of tree proxies) some unexpected changes in response that do not match the recent warming. I do not think it wise that this issue be ignored in the chapter.

For the record, I do believe that the proxy data do show unusually warm conditions in recent decades. I am not sure that this unusual warming is so clear in the summer responsive data. I believe that the recent warmth was probably matched about 1000 years ago. I do not believe that global mean annual temperatures have simply cooled progressively over thousands of years as Mike appears to and I contend that that there is strong evidence for major changes in climate over the Holocene (not Milankovich) that require explanation and that could represent part of the current or future background variability of our climate. I think the Venice meeting will be a good place to air these issues.

Finally I apologise for this rather self-indulgent ramble, but I thought I may as well voice these points to you . I too would be happy to go through the recent draft of the chapter when it becomes available.

cheers to all
Keith

Thanks for your comments Phil,

They look quite reasonable, and I will seek to incorporate them. I'll need Keith's comments by tomorrow morning (my time) at the very latest if I am to have time to assess them and incorporate them.

Some important specifics:

1) I am definitely using the version of the Briffa et al series you sent in which Keith had restandardized to retain **more** low-frequency variability relative to the one shown by Briffa et al (1998). So already, the reconstruction I'm using is one-step removed from the published series (as far as I know!) and that makes our use of even this series a bit tenuous in my mind, but I'm happy to do it and let the reviewers tell us if they see any problem. If I understand you correctly, there is yet a new version of this series that is two steps removed from Briffa et al (1998)? Frankly, at this stage I think we have to go w/ what we have (please see Ian Macadam's plot when it is available--I think the story it tells isn't all that bad, actually) for the time being. Things as you say will change following review anyways.

2) One other thingp--I'm actually averse to shortening the section on sediments. Even if they haven't contributed to some of the multiproxy studies (they certainly **did** contribute to Overpeck et al!) there are some important results there irrespective of the role of the proxies in multiproxy studies. Lets, again, wait for reviews before shortening this...

3) We could eliminate the map of the boreholes, although I actually think it is essential to see what the contributing spatial sampling (and, accordingly, the potential bias of that sampling in determining "global mean temperature") actually is. So I vote for keeping it for the time being. Again, it's an extremity that we can afford to lose if necessary in the end..

4) One important note on references: We don't have time at this late stage to dig up incomplete citations, so you'll need to give me full citations for any suggested added references (e.g. the Villalba paper). FYI, the Crowley and Lowery paper is Tom's Ambio paper. He observes a mean warming of about 0.5 C since the 17th century giving us yet another datapoint in the scatter of estimates...

5) I agree, the ranking of centuries is more specific than it needs to be. I don't know what I was thinking. You sure that didn't come from the text you originally contributed?? In any case, we can eliminate much of it in my opinion too...

On the whole, I have never been under the assumption that you and I would have independently assessed the evidence quite the same way. I would hope we would have come up w/ the same key points, and so your comments in that regard are reassuring. I feel confident in my ability to defend the science that is presented here, so let the reviews fall where they may. I'm sure we will be forced to admit some changes, as well as "minority viewpoints" and alternative interpretations along the way. That's what will make this all interesting...

Thanks alot Keith,

Your comments and suggestions sound good on all counts.

Clearly there is one overiding thing to make sure of here: that we have the right version of your series. I **think** that we do, and you might have been looking at an old version of the comparison Figure??

Please check out the data here ASAP:

<ftp://eclogite.geo.umass.edu/pub/mann/IPCC/MILLENNIUM/>

This directory has all the series, aligned as I described to have a 1961-90 base climatology (or in the case of your series, a pseudo 1961-90 base climatology achieved by actually matching the mean of your series and the instrumental record over the interval 1931-60 interval). These are the data that Ian Macadam is hopefully presently plotting up, and I don't think the discrepancies between the different series are as bad as we percieved earlier (other than the late 19th century where you are somewhat on the warm side relative to the rest). Please confirm ASAP that we have the right version of the series (note, these have all been 40 year lowpassed)...

One other thing, I think you misinterpreted my statement:

>
>SO I think we're in the position to say/resolve somewhat more than, frankly,
>than Keith does, about the temperature history of the past millennium.
>And the issues I've spelled out all have to be dealt with in the chapter.
>

I wasn't talking about the comparison of our two series! I was talking about our two different opinions on how confident we are about our ability, as a community, to assess the actual climate changes over this timeframe. And perhaps we're closer here than I assumed anyways. Sorry about the misunderstanding. With your interpretation, my comment must I have sounded really obnoxious!

Mike,

Here are my thoughts on the text you sent. Keith will be sending some as well hopefully later today. One important aspect Keith will address is whether you're using the latest Briffa et al curve. We know you're not but the one with the greater low frequency and therefore much better chance of looking much better with the other two series, isn't yet published. We know it looks better in plots we have here.

Specifics :

p1 line 10 - say mid-19th century rather than the 20th century

lines 18-20 - seems a bit too much here with three refs on laminated sediments.

line 46 Add Briffa et al (1998b) to Cook(1995).

p2 line 59 - I would suggest changing 'a particularly' to 'the most' .

line 64 - I would add a reference here to the paper by Crowley and Kim (1999) in GRL (July) where this aspect is also discussed.

p3 line 101 - I would add Argentina as well as Chile adding a ref to Villalba (1990) in QR.

line 108 change 'key' to 'vital'

line 119 'have providing' to 'provide' . There are several instances where the text doesn't read that well. I suspect as there are several iterations to go it is not that important yet !

The coral section is just about the right size now and is justly devoid of references !

p4 line 151 I would add a reference here to Morgan and van Ommen (1997) 'Seasonality in late-Holocene climate from ice core records', The Holocene 7, 351-4. This is the Law Dome core which is the best available with regards to dating in either hemisphere. It should be there.

As with the coral section the ice core section expresses some cautionary notes with regard to dating etc which I think are justified. I suspect the contrast with the tree-ring section will draw some criticism. Just a warning !

As none of the multiproxy reconstructions use any sediment information this section seems overlarge and could be reduced.

p189 century-scale add in the 'y'

p5 The borehole section is also a bit overlong. I don't know whether the map really adds something. Not that vehement on this.

With respect to comparing high and low frequency aspects the diagram comparing CET with the UK boreholes is now out. I've sent a copy to Chris. It is in :

Jones PD, 1999 : Classics in physical geography revisited - Manley's CET series. Progress in Physical Geography 23, 425-428.

line 245 the 'is' is not needed.

p6 I still think that a reference to Raper et al (1996) would be good here. This models a glacier in northern Sweden using the northern Fennoscandian temperature reconstructions since AD 500. Again it shows how a low frequency estimate (the glacial snout position) can be compared with a high-frequency temperature reconstruction from trees.

Raper, SCB, Briffa KR and Wigley TML, 1996: Glacial change in northern Sweden from AD 500: a simple geometric model of Storglaciaren. Journal of Glaciology 42, 341-351.

line 268 IPCC(1996) earlier - is it 95 or 96

p 7 line 295 I would like to add my paper in Reviews of Geophysics in 1999 as that also says that 1998 was likely to be the warmest year of the millennium.

line 334 I would like to see Bradley (1999). I must get a copy from Ray in Venice.

p7-9 All need a careful read through for English and the arguments.

At the bottom of p8 I think you make too much of the differences in the ranking of the centuries. The boreholes would agree with my series with the 17th being colder than the 19th, although they may not be able to resolve the timescales then.

Is the Crowley and Lowery (1999) the paper Tom's submitted to Ambio ?

I've not commented much on this final section as again I suspect there are many things you will have to justify in the next two sets of reviews. On the whole I think most is OK and I support the final paragraph. I don't believe the astronomical argument as an explanation over the last 1000 years but we can differ on that.

I know I would have written this final section 2.3.3 somewhat differently with different emphases and slants but the basic final conclusion would have been the same.

Cheers
Phil

Dear Mike (and all)

Some remarks in response to your recent message

I believe strongly that the strength in our discussion
>will be the fact that certain key features of past climate estimates are
>robust among a number of quasi-independent and truly independent
estimates,
>each
>of which is not without its own limitations and potential biases

Mike , I agree very much with the above sentiment. My concern was
motivated by the possibility of expressing an impression of more
consensus than might actually exist . I suppose the earlier talk implying
that we should not 'muddy the waters' by including contradictory evidence
worried me . IPCC is supposed to represent consensus but also areas of
uncertainty in the evidence. Of course where there are good reasons for
the differences in series (such as different seasonal responses or
geographic bias) it is equally important not to overstress the
discrepancies or suggest contradiction where it does not exist.

And I
>certainly don't want to abuse my lead authorship by advocating my own
work.
>

I sincerely hope this was not implied in anything I wrote - It was not
intended

>I am perfectly amenable to keeping Keith's series in the plot, and can
ask
>Ian Macadam (Chris?) to add it to the plot he has been preparing
(nobody
>liked my own color/plotting conventions so I've given up doing this
myself).
>The key thing is making sure the series are vertically aligned in a
reasonable
>way. I had been using the entire 20th century, but in the case of
Keith's,
>we need to align the first half of the 20th century w/ the corresponding
mean
>values of the other series, due to the late 20th century decline.
>

Again I agree. Also , I am not sure which version of the curve you are now referring to. The original draft did show our higher frequency curve i.e. the version with background changes effectively filtered out (intended to emphasise the extreme interannual density excursions and their coincidence with volcanic eruptions) . The relevant one here is a smoothed version in which low-frequency changes are preserved. I can supply this and it will be in press by the time of the next reworking of the text.

Your above point on correct scaling is relevant also to Phil's curve which was not originally calibrated (in a formal regression sense) with the summer temperature data - it was just given the same mean and standard deviation over a specific period. Hence the issue of equivalent scaling of all series is vital if we are to discuss specific period temperature anomalies in different series or compare temperature trends in absolute degrees.

>So if Chris and Tom (?) are ok with this, I would be happy to add Keith's series. That having been said, it does raise a conundrum: We demonstrate (through comparing an extratropical averaging of our northern hemisphere patterns with Phil's more extratropical series) that the major discrepancies between Phil's and our series can be explained in terms of spatial sampling/latitudinal emphasis (seasonality seems to be secondary here, but probably explains much of the residual differences). But that explanation certainly can't rectify why Keith's series, which has similar seasonality and latitudinal emphasis to Phil's series, differs in large part in exactly the opposite direction that Phil's does from ours. This is the problem we all picked up on (everyone in the room at IPCC was in agreement that this was a problem and a potential distraction/detraction from the reasonably consensus viewpoint we'd like to show w/ the Jones et al and Mann et al series.

>

I am not sure this is true if the relevant series of ours is used. We need to reexamine the curves and perhaps look at the different regional and seasonal data in the instrumental record and over common regions in the different reconstructed series. We would be happy to work with you on this. Also remember that our (density)series does not claim hemispheric or annual coverage.

>So, if we show Keith's series in this plot, we have to comment that >"something else" is responsible for the discrepancies in this case. Perhaps Keith can help us out a bit by explaining the processing that went into the series and the potential factors that might lead to it being "warmer" than the Jones

>et al and Mann et al series?? We would need to put in a few words in
>this
>regard. Otherwise, the skeptics have an field day casting
>doubt on our ability to understand the factors that influence these
>estimates
>and, thus, can undermine faith in the paleoestimates.

The best approach here is for us to circulate a paper addressing all the
above points. I'll do this as soon as possible.

I don't think that
>doubt is scientifically justified, and I'd hate to be the one to have
>to give it fodder!
>
>
>The recent Crowley and Lowery multiproxy estimate is an important
>additional piece of information which I have indeed incorporated into
>the
>revised draft.
>Tom actually estimates the same mean warming since the 17th century in
>his
>reconstruction, that we estimate in ours, so it is an added piece of
>information that Phil and I are probably in the ballpark (Tom has used
>a somewhat independent set of high and low-resolution proxy data and a
>very
>basic compositing methodology, similar to Bradley and Jones, so there is
>some independent new information in this estimate.
>

fair enough - but I repeat that the magnitude of the observed warming in
the 20th century is different in summer and annual data

>One other key result with respect to our own work is from a paper in the
>press in "Earth Interactions". An unofficial version is available here:
>
>http://www.ngdc.noaa.gov/paleo/ei/ei_cover.html
>
>The key point we emphasize in this paper is that the low-frequency
>variability in our hemispheric temperature reconstruction is basically
>the
>same if we don't use any dendroclimatic indicators at all (though we
>certainly resolve less variance, can't get a skillful reconstruction as
>far
>back, and there are notable discrepancies at the decadal and interannual
>timescales). I believe I need to add a sentence to the current
>discussion
>on this point,
>since there is an unsubstantiated knee-jerk belief that our low-
>frequency
>variability is suppressed by the use of tree ring data.
>
>We have shown that this is not the case: (see here:
>http://www.ngdc.noaa.gov/paleo/ei/ei_datarev.html

>and specifically, the plot and discussion here:
>http://www.ngdc.noaa.gov/paleo/ei/ei_nodendro.html
>Ironically, you'll note that there is more low-frequency variability
when
>the tree ring data *are* used, then when only other proxy and
>historical/instrumental data are used!
>

This is certainly relevant and sounds really interesting. I need to look at this in detail. The effect of the including tree-ring data or not, is moderated by the importance of the particular series in the various reconstructions (relative coefficient magnitudes). There is certainly some prospect of affecting (reducing) the apparent magnitude of the 20th century warming by loading on high-pass filtered chronologies , but equally a danger of exaggerating it if the series used or emphasised in th calibration have been fertilized by CO2 or something else. As you know we (Tim, Phil and I) would love to collaborate with you on exploring this issue (and the role of instrumental predictors) in the various approaches.

The key here is knowing much more about the role of specific predictors through time and their associated strengths and weaknesses.

>SO I think we're in the position to say/resolve somewhat more than,
frankly,
>than Keith does, about the temperature history of the past millennium.
>And the issues I've spelled out all have to be dealt with in the
chapter.
>

I certainly do not disagree with you - the scale of your input data undoubtedly must contain more information than our set . I have never implied anything to the contrary. I do not believe that our data are likely to tell us more than summer variability at northern latitudes . The discussion is only about how close our and your data likely represent what they are calibrated against , back in time. Let's not imagine a disagreement where there is none.

>One last point: We will (like it or not) have SUBSTANTIAL
>opportunity/requirement to revise much of this discussion after review,
so
>we don't have to resolve everything now. Just the big picture and the
>important details...
>
>I'm sure we can can up with an arrangement that is amenable to all, and
I'm
>looking forward to hearing back from Keith, Phil, and Chris in
particular
>about the above, so we can quickly move towards finalizing a first
draft.
>

>

Yes indeed. The reviewing will lead to much comment and likely disagreement by the masses. This is the way of these things. It is always a thankless task undertaking these drafting jobs and I think you are doing a good job. Tommorrow I'll send some very minor comments on typos and the like if you want them - or have you picked many of them up? Anyway , keep up the good work .

best wishes

Keith

Subject: crossdating difficult tree-ring series
Date: Thu, 30 Sep 1999 13:21:13 -0700
Reply-to: grissino@VALDOSTA.EDU

Forumites,

Ouch, my hackles are rising so high, it hurts. (Just what exactly are hackles, anyway?).

Yes, computer crossdating ring series with special problems is always dangerous. But this is where good old skeleton-plot dating with intensive and thorough visual examination of the WOOD becomes the way to go.

I don't know about Thuja, but with the Juniperus species in the U.S. I've worked with, rings piching in and out can be a problem. You can lose 50-100 rings that way, sometimes. However, a different radius of the sample may possess all those absent rings. It's nice to have a cross-section of the subject tree, though I know this isn't always possible.

I don't understand physiologically what's going on with the Canadian cedars, but dendrochronologically speaking, absent rings are absent rings, no matter what the reason for the rings not forming on any given portion of the tree. I'll leave the reasons to scientists like Frank Telewski.

I do know that with some dying trees -- like the pinyons from New Mexico that died in the Great 1950s Drought -- the ring series on the outside became so suppressed that individual rings were indiscernable. Fortunately, other trees growing in more favorable spots had distinguishable -- though still suppressed -- rings. Traditional skeleton-plot croosdating -- along with its concomitant intensive visual analysis -- made it possible to sort though these problems.

I am not, however, an America-centrist skeleton-plot-dating bigot! I have a true appreciation for computer crossdating where it is appropriate and indeed necessary. I myself was recently involved dating high-elevation bristlecone pine from northern Arizona, U.S.A.

The multi-millennial length of the chronology -- as well as the freedom from absent rings and the presence of frost-year marker rings -- made computer crossdating advisable. Of course every significant computer dating correlation was thoroughly checked out on the WOOD, and if the visual characteristics of the tree rings themselves did not support the computer dating, we threw out the date -- right out the window. Discarded computer dates collected on the parking lot beneath our offices and needed to be hauled off to the dump everyday.

I apologize for the aggressive (though sincere) tone of this message, but every few years I feel the need to rant and rave about the importance of WOOD and "pure" forms of crossdating.

Best Regards,

Jim Parks

Subject: national climate change centre meeting - documents
Date: Sun, 3 Oct 1999 22:19:48 +0100
Cc: <m.hulme@uea.ac.uk>

Dear All,

Here are some notes and suggestions for our national climate centre meeting on Monday morning (1000hrs). A suggested agenda of the main points we need to cover is in this email. The attached document has three components (also appended as text to the email):

A suggested Outline Bid structure with some comments/questions
A draft of a possible 600-word opening statement
A draft of the six (from original four) research challenges (ca. 2,400 words)

We really need to aim to get a first full draft of the bid out to our Partners by late Wednesday this week, thus allowing 7 days for iterations.

Mike

NCCC: UEA Working Group Meeting, 4 October

Suggested Agenda

1. The research challenges (draft attached)
2. RD and Schneider (?)
3. The Assessment Panel; key issues for Schellnhuber
4. The structure of the outline proposal (see attached suggestion)
5. The name of the Centre
6. Timetable for submission (8 working days left)

**

Outline Proposal
Suggested Contents – cf. invitation to bid

Opening Statement (500 words)

Who are the co-applicants?
Hulme, Davies, Jones, Liss, Palutikof, Parry, Turner, Watkinson, Brown?
Allen, Arnell, Berkhout, Bristow, Cannell, Choularton, Halliday, Jenkins,
Kohler, Launder, Markvard, Reynard, Shepherd, Shackley? – is this too many?

The strengths of the UEA-led Team (1000 words)
- being drafted by UMIST

Research Director 100 words

Management team, structure, strategy (500 words)

Advisory Board - Hasselmann, Rotmans, McQuaid, Mary Archer (Chair of National Energy Foundation), Basil Butler (RAE), Wigley, and named others? Management Team, Programme Leaders, What building do we use? – and a suggested physical presence at Southampton and UMIST

Initial research plan/agenda - the Challenges (2000 words)
0-order draft (attached)

How will we achieve - integration, collaboration, exploit results, attract funding? (500 words) (this might be folded into the discussion of the strengths of the UEA Team)

integrated research

formal or informal integration; IAMs are one way, but I'm not so keen on them. Some research themes may develop their own limited IAMs, e.g. optimal policy. Overall informal integration may be achieved through a

common scenario approach/framework

collaboration in UK and abroad

establish MoUs with parallel centres abroad – RIVM (Neth.), PIK (Germany), ICIS (Neth.), MIT (US), Batelle (US), TERI (India), CICERO (Norway), etc. Host an international conference early on to 'position' the UK NCCC in the wider field.

relevant and strategic research results and knowledge-transfer

establish regular policy briefings, both written and verbal, targeted at the business community; CBI link; UKCIP. Have a strong media presence, with a p-t communications person.

attract additional funding

may be not so easy, cf. UKCIP on impacts research have only been able to mobilise small amounts of money. Need some big corporate sponsors – what do we say about this in the outline bid?. Appoint a p-t 'marketing' person (maybe the other half of communications).

Training strategy (250 words)

Ring-fence money for training/workshops/fellowships - how much?

Training not just for researchers, but also for managers in public/private sectors. These could be 1-day sessions, as well as longer 1-week courses (cf. the Harvard course), and also longer-term secondments.

Should also maximise our links with the B.Council and DfID to bring international scientists and policy-advisors into the loop. These people can act to facilitate the two-way flow and testing of ideas between UK and developing countries. Some of our research themes would have global dimensions – optimal policy, C sequestration,

UNESCO Southampton

Financial plan - salaries, equipment, sub-contracted research, collaboration expenses
- estimates from Trevor

Operations timetable - phases, etc.
- what ideas do we have for this?

Other contacts

institutions involved, but outside the bid
BRE, BAS, NRI, POL, LSHTM, AEA, Hadley Centre, UKCIP, etc.

other academic/user bodies who are relevant
RIVM, ICIS, TERI, RDBs, BP, Fuji, PowerGen, BP Solarex, ETSU/DTI
photovoltaic test facility, Severn-Trent,

Appendix

1 page CVs for co-applicants
signed statement from institution(s)

[extraction of purpose from the RC's document the integration of scientific research that will shape and underpin sustainable solutions to the climate change challenge].

Possible Opening Statement

The prospect of human-induced global climate change initially emerged as a research challenge for the natural sciences. Since the causes of climate change are profoundly rooted in society and the consequences of climate change for society can only be understood through social and cultural insight, the social sciences have become increasingly engaged in the research effort. With attention now turning to 'solutions' to climate change, new climate change management strategies need identifying and promoting, need to be targeted at both mitigation and adaptation objectives, and need to embrace a full array of emerging policy instruments and engineering technologies. The participation of the engineering and technological sciences, alongside the environmental and social sciences, has therefore become critical to meet this rapidly evolving research agenda.

But climate change is not just intellectually embracing challenge. It is also an experiential one. Climate change is unique in that it poses questions on space and time scales over which individual humans (especially space) and governments (especially time) are not used to thinking or do not find it easy to think. In this sense climate change is a problem of ultimate penetration and of ultimate connectivity; penetration, because we will all experience and react to climate change in some way, and connectivity, because emissions are driven by a global economy, because the response of the physical system is planetary, and because these social and natural systems are intimately co-evolving.

The intellectual and experiential challenges of climate change create a new and distinctive lens through which we can envision the future. These insights into the future - often termed scenarios - suggest to us various tools and instruments that may allow us to fashion and shape the future. This sets us out on a course of climate change management, an active and considered pursuit of desirable long-term objectives. Establishing such objectives is essential in order to adequately define the 'problem' of climate change, and even more essential if 'solutions' to this problem are going to be designed. The prospect of climate change, at the very least therefore, forces us to think about what sort of future we regard as desirable.

The UEA-led Consortium sees the new national climate change centre as an exciting opportunity to build connected research structures and outputs that exploit partnerships between science and business, between the household and government, and between the UK and emerging parallel initiatives around the world. With a strong foundation of inter-disciplinary research, and through the engaging of both public and private organisations and of both governments and individuals, there is a real prospect that we can implement emerging 'solutions' to climate change and create new ones. These 'solutions' need to engage with both mitigation and adaptation objectives and, most importantly, need to recognise and function on a hierarchy of scales ranging from the household to the global. The UK climate change centre will be built around three key principles:

The deployment of practised, inter-disciplinary research teams, who have already pioneered new insights and approaches into the questions raised by climate change, but releasing them to explore novel approaches for thinking laterally across natural, social and engineering sciences.

The practising of an inclusionary process of research in which we explore - with their developers - ways of mobilising many of the new technologies, lifestyles, regulatory mechanisms that are emerging from our technological, social and political cultures to allow us to manage climate change in the twenty-first century.

The establishment of a focal point in the UK and abroad for the open and constructive exchange of insights concerning climate change solutions across cultural divides - public-private, households-corporations, North-South.

These three key characteristics - a research programme, an engagement with stakeholders, and an educational/opinion-shaping role - are the three central elements of the new centre as proposed by the UEA-led Consortium. [Given the essential need for integration in all three of these elements, we propose the centre be called the "UK Centre for Integrated Climate Change Studies" (UK CICCSS)]. The rest of this outline proposal will demonstrate, in an indicative rather than an exhaustive way, how we would operationalise these principles in terms of both management and research ideas. [refer to our conceptual schematic here or later?]

Proposed Challenges to be included in the Outline Bid

Draft, Mike Hulme, 2 October

[It may be worth including some examples of key stakeholder/client interests under each of these. These six research challenges are exemplars, for the outline proposal, of the thinking behind our bid. Each of them may potentially involve all of the Centre's Partners - and numerous organisations beyond - and each of them are therefore integrating activities. Each of these Challenges, if developed into Research Programmes, would have a Programme Leader, appointed from within the Consortium, and accountable to the Centre's Management Team. Each of the Challenges should be able to be contextualised by our (revised) conceptual schematic of the process of integration - if we are still going to show this.]

Challenge 1: Carbon Management

Carbon management poses two fundamental questions. Given a continuing pre-dominance of fossil carbon fuels how can we combust less (the energy efficiency question) and given that a proportion of this combusted carbon will enter the atmosphere how can we sequester larger volumes within the biosphere and oceans (the carbon sequestration question)? In thinking about improving our management of carbon, the Centre will address both these questions.

Combined heat and power plants and decentralised energy generation for energy intensive industries are areas where technology can make a considerable contribution to emissions reduction. Locations and markets where investment in these technologies is both politically and economically feasible need to be identified. For LDCs, the provisions of the Kyoto Protocol for Joint Implementation are relevant here. Supplementary engineering challenges in this area include energy storage systems, fuel cell and novel transportation technologies.

Research should also be directed to the identification of business opportunities in the mitigation of climate change. This would involve a process of identifying 'climate change markets' where UK products and technologies could be supplied. One potential growth area is that of the use of modern, cheap control technology to optimise the performance of household energy management systems. Where growth markets are identified, suitable technology and service products can be developed. Business could be approached for ideas through the DTI-funded liaison officer. This work would also inform development and aid policy within the UK government. We would also draw upon the extensive experiences of UK agencies involved in delivering 'win-win' energy and waste minimisation programmes (such as Energy Efficiency and Environmental Technology Best Practice Programmes, Ground Work Trust, Business Links, and so on). Other country experiences would also be useful input, for example the highly effective programmes of boosting company productivity by reducing greenhouse gas emissions developed in the USA.

The introduction of the climate change levy in March 2001 will be analysed by the Centre in terms of its effectiveness at delivering emission reductions and its costs/benefits to a range of units (firms, sectors, regions, nationally). In addition, the introduction of voluntary agreements for some companies in return for a reduction in the levy charged will be analysed along similar lines. The DTI-ACBE led initiative on voluntary use of tradeable emission schemes will provide important empirical evidence on the relative costs of achieving given emission reductions by a taxation scheme compared to emissions trading.

While conventional carbon sequestration technologies are not considered a long-term solution to climate change, there is nevertheless a need to research the most efficient ways of implementing such technologies and also a need to research new, longer-term sequestration technologies through bio-engineering and deep ocean sinks. The Centre will explore the feasibility of both these latter two technologies, in collaboration with the John Innes Centre for the bio-engineering. [We may only have 30 years to get some 'emergency' carbon sequestration techniques sorted out under the scenario that we don't manage to get enough CO₂ emissions reduction.] A mixture of methods and tools will be required to evaluate sequestration options - life-cycle costing and LCA, environmental impact analysis, technological assessment, public acceptance, etc. Some work on biomass sequestration may also be needed to feed into the global

assessments/evaluation of this option. Given the sensitivity of this issue under the terms of the Kyoto Protocol, the UK government needs excellent advice on methods, assumptions, pitfalls, etc.

[Links outside the Centre to: JIC, many others

Challenge 2: The Renewables Challenge

A parallel challenge to that of carbon management is how to stimulate and release the full potential for zero- or low-carbon renewable energies? This therefore is the third strand of the strategy to meet and surpass the carbon emissions reduction obligations placed on developed nations by Kyoto. There are a number of research questions related to this Challenge that again require engagement by the engineering, environmental and social science communities within an integrated framework. Too much work to date has compartmentalised the three perspectives.

The EU has a target of 12 per cent of primary energy to be met from renewable energy by the year 2010. Meeting such a target, let alone moving beyond it, has major implications for the electricity delivery systems in the UK. How to get this much renewable energy - from intermittent sources - linked, delivered and purchased by customers? Engineers and economists need an opportunity to explore the long-term implications of such policy objectives. Related questions concern the landscape and infrastructural implications of an expanded uptake of biofuels in the UK.

Many renewable technologies appear in various EPSRC research programmes, but they need to be brought together to produce scenarios whose emissions and life-cycle costs can be assessed in a common framework, thus enabling more practical advice and comment on energy policy debates. Some of these scenarios could be taken further in the form of pilot-demonstration projects.

There needs to be mechanisms established for the better integration of architectural design with renewable energies, e.g. solar and wind. The design of these new technologies needs explicitly to consider the architectural consequences for domestic, commercial and industrial structures. Partners who are directly involved in delivering design solutions in this area will be invited by the Centre to establish 'demonstration' projects to explore how successful such solutions are in practice. [can we give some specific examples of Partners and projects here?]

One of the obstacles to the more rapid exploitation of wind energy in the UK relates to landscape value and aesthetics. This is an issue that needs the interaction of design technologists and social scientists - including psychologists - to explore cultural and behavioural limits to new renewable technology uptake. We propose that the visualisation facility of the Centre be exploited to research these issues through involving the wider community.

[Links outside the Centre to:

Challenge 3: Singularities, Non-Linear Changes and Extreme Events

The climate system is generally assumed to be 'well-behaved'. Certainly, much of the scenario and impacts work assessed by the IPCC (and that has

therefore fed through into climate policy) has assumed conditions of relative regularity in future climate. However, not only does the climate system possess the potential for rapid, singular changes (i.e., a complex, non-linear system being rapidly forced), but recent research has shown using theoretical models and palaeo-evidence that such potential changes can be and have been realised. Elsewhere, thresholds and sensitivities of natural/social systems to changing frequencies of extreme weather events induce additional non-linearities in the environmental responses to climate change. There are also singularities and non-linear processes operating in the social/political drivers of climate change - for example, political or economic 'shocks' that may fundamentally and rapidly re-direct our technological/economic futures away from 'conventional' pathways.

A particular Challenge to be addressed by the Centre will therefore be how such potential for non-linear behaviour - in both climate and non-climate systems - can be both modelled and introduced into scenario exercises. Recent work with reduced-complexity models has shown the potential to model such non-linear behaviour in a quasi-stochastic manner and such modelling work will be developed by the Centre. A corollary of this is to better understand how such abrupt changes should be assimilated into decision-making frameworks and policy analysis. This requires the involvement of risk theoreticians and risk analytic tools. The possible interactions between these two complex non-linear systems - the climate and the social - is of particular importance. For example, an abrupt climate change or a string of short-term weather extremes can radically influence perceptions amongst the business community and politicians and lead to sudden shifts in policy, investment flows, etc. The implications of such singular behaviour for vulnerability and adaptation strategies have not been well explored. This kind of analysis would be important to many commercial sectors, which are highly concerned about the unexpected and about extremes. This is an inter-disciplinary Challenge the Centre will be uniquely well-placed to address.

[Links outside the Centre to: POL, Hadley Centre, PIK,

Challenge 4: Managing the Coastal Zone

There are many geographic domains where climate change poses particular problems for the management of natural and social assets - coasts, uplands, cities, river basins, etc. We propose that the Centre should pay particular attention to one such domain, since these provide physical entities within which many of the issues of climate change vulnerability and adaptation play out in a given context of local/regional governance. We suggest that the coastal zone best epitomises this challenge of integrating our social, environmental and engineering knowledge. A unique feature of the interaction between climate change and the coastal zone is the very long time-scales over which sea-level rise impacts will materialise - of all the impacts of climate change these are least amenable to mitigation and therefore where appropriately designed adaptation strategies are most needed.

Research is first needed to improve our understanding of the threats posed by climate change, most notably changing storm-surge frequencies along the UK coast and changes in estuarine hydrology and ecology. This will involve coupled high resolution ocean-atmosphere modelling, estuarine economic/ecological modelling, and the assimilation of such modelling results into a risk analysis framework.

Designing an array of possible management options for the coastal zone needs to involve economists, ecologists, marine scientists, and coastal engineers. A range of options from 'hard' engineering solutions to managed retreat need identifying. The desirability of any one or combination of these management options for the coastal zone can then only be evaluated following an understanding of the value of the coastal environment and the services it delivers. Such valuation needs to be a fully participatory process involving local communities, local government, landowners, NGOs, and national regulatory bodies. We propose the Centre plays an active role in bringing together insights from integrated modelling exercises and from stakeholder participatory exercises, thus enabling better public participation in the policy-forming process (see integration methodologies - Challenge 6). This role would involve novel visualisation techniques of coastal environments to exploit both modelling results and individual perceptions of coastal landscape value.

[Links outside the Centre to: EA/MAFF, NGOs/Conservation, LAs, Railtrack, construction companies,

Challenge 5: Beyond Factor 4

There is a growing body of opinion that in order to mitigate climate change, or even to adapt to it, significant changes in current patterns of consumption, and therefore lifestyle, are necessary. This raises the question of how to direct consumption of goods and services towards more sustainable paths. The scale of the Challenge here suggests that we need to go well beyond Factor 4 - doubling wealth, halving resource use.

One unsolved dilemma is that of expanding car use for personal transportation. The psychology, behavioural sociology and economics of people's use of cars is reasonably well understood. What needs to be researched are methods to manage the ever-increasing demand for travel, especially car and air travel, that ranges from taking the children to school, to car-based salespeople, to international business and holiday travel. Research will also be needed into managing the overturning of the vehicle stock and transport infrastructure under conditions of novel transportation technologies - infrastructural inertia is an obstacle to new technology uptake.

The concept of a low consumption household is a further desirable objective which is easy to state and not straightforward to achieve. This way of analysing human activity is inherently interdisciplinary and looks at the activities of a household - housing, domestic appliances and services, transport needs, consumption, work and leisure time use, waste generation and recycling - in terms of the interactions between them. For example, housing choice is partly determined by the work/leisure split, which then determines the demand for transport; consumption generates waste and also contributes to energy demand. Another important example is that of home insulation. The UK has a poorly insulated housing stock and even new housing could be built to much higher standards of energy efficiency. Research, in conjunction with the construction industry, is needed into the adoption of new building standards and (politically acceptable) economic incentives for low-energy housing is needed. This is especially relevant given the current debate about the millions of new households predicted for the UK in the next 20-30 years and the greenfield/brownfield land use argument.

Partners who are directly involved in delivering sustainable solutions will be involved in setting up 'demonstration' projects to explore how

successful such methodologies are in practice. For example, the Centre will explore whether 'climate-friendly' households can be demonstrated in practice. Partners could include Going for Green, National Centre for Business and Ecology, Forum for the Future, Sustainability Northwest, United Utilities, Eastern Group, Anglian Water and other water companies, etc.

[Links outside the Centre to:

Challenge 6: Integration Methodologies

An important methodology which provides insights into the dynamics of climate and social change, but which has not yet been fully developed for the UK is that of integrated assessment. Integrated assessment encompasses formal modelling approaches and more participatory and qualitative explorations of the future. Integrated modelling includes both reduced-form models and complex systems models. All integrated assessment is built around the concept of scenarios, used either in the more traditional role of 'what-if' or in a 'back-casting' role. While integrated assessments of climate change have developed substantially over the last decade, few have embraced the engineering community to explore the feasibility of pathways with rapid uptake of new technologies. The Challenge for the Centre will be to develop further existing modelling and participatory approaches for integrated assessment and apply them to the five research Challenges identified above.

The integrated modelling framework that is required to address these concerns is obviously extremely difficult to imagine. Recent advances based on complex systems modelling do, however, suggest how such frameworks may be achieved (e.g. NEXSUS, ESRC Priority Network). These are constituted of a spatial hierarchy of nested models representing the possible behaviours of complex social, economic, ecological, and technological systems at different spatial and temporal scales of resolution. They can explore the possibility of emergent behaviour at larger scales, as well as the effects of micro-responses and adaptations at smaller ones. In order to address the issues raised by climate change and its associated impacts and responses, considerable development of this framework would be necessary. However, without it, there seems little prospect of providing a rational basis for the assessment of possible climate policies or actions.

The Centre will also develop parallel research into participatory approaches for the development of integrated scenarios of the future. This will include the public perception of environmental risks caused by climate change; peoples actions in response to these perceptions is also important. Identification of suitable scenarios for presentation in participative experiments on public/corporate response would involve the physical sciences in co-operation with engineers, political scientists, psychologists and economists. Methods include surveys, focus groups, citizens juries and stakeholder workshops. [CSERGE/UMIST developing these ideas; use the ICER Visualisation Laboratory]. More in-depth empirical research could be undertaken to understand better individual and organisational decision-making on climate change related issues, such as energy consumption, transport choices, and so on. This activity would have the objective of developing methodologies for assessing the public response to the particular problems identified in the Carbon Management, Renewables and Factor 4+ Challenges above. Through interactions with business it may also open up the possibility of 'design-oriented scenarios', i.e., in which the scenario identifies a need for a new kind of product/process design in response to a prospective future socio-political change.

Attachment Converted: "c:\eudora\attach\outline.bid.doc"

From: "Michael E. Mann" <mann@multiproxy.evsc.virginia.edu>
To: Tim Osborn <t.osborn@uea.ac.uk>, imacadam@meto.gov.uk
Subject: Re: Briffa et al. series for IPCC figure
Date: Tue, 05 Oct 1999 12:31:56 -0400
Cc: k.briffa@uea, p.jones@uea, ckfolland@meto.gov.uk, tkarl@ncdc.noaa.gov

Dear Tim,

Thanks for the information. I don't want to speak for Tom Karl, but I think it may be a bit too late (past the Oct 1 deadline) to make further revisions in the draft 1.0. It would be a bit of an imposition on Tom at this point given what he's been through in finalizing the draft. However, I see no reason that we can't make that revision when the paper comes back from expert review in a couple months. We'll have the further advantage that the supporting manuscript you describe should be available at that point (a requirement in the IPCC peer-review process). I think we'll all be looking forward to updating the plot w/ the latest series you describe...

As for decisions about the most appropriate baseline period to use for the series, that is as you point out an important issue and one we have to consider with some circumspection, especially if a "modern" calibration (e.g., 1931-1960) to the instrumental record gives a substantially different alignment from the more 19th century-oriented calibration you describe. The tradeoff of course is that the instrumental series itself is considerably less certain prior to the 20th century while, as you point out, the non-climatic influence on tree growth may be setting in by the mid 20th century. Something I think we can iron out satisfactorily at the next juncture.

I hope the above sounds ok to you guys. Let me know. Thanks,

mike

Subject: Briffa et al. series for IPCC figure
Date: Tue, 05 Oct 1999 16:18:29 +0100
Cc: k.briffa@uea,p.jones@uea

Dear Mike and Ian

Keith has asked me to send you a timeseries for the IPCC multi-proxy reconstruction figure, to replace the one you currently have. The data are attached to this e-mail. They go from 1402 to 1995, although we usually stop the series in 1960 because of the recent non-temperature signal that is superimposed on the tree-ring data that we use. I haven't put a 40-yr smoothing through them - I thought it best if you were to do this to ensure the same filter was used for all curves.

The raw data are the same as used in Briffa et al. (1998), the Nature paper that I think you have the reference for already. They are analysed in a different way, to retain the low-frequency variations. In this sense, it is one-step removed from Briffa et al. (1998). It is not two-steps removed from Briffa et al. (1998), since the new series is simply a *replacement* for the one that you have been using, rather than being one-step further.

A new manuscript is in preparation describing this alternative analysis method, the calibration of the resulting series, and their comparison with other reconstructions. We are considering submitting this manuscript to J. Geophys. Res. when it is ready, but for now it is best cited as:
Briffa KR, Osborn TJ, Schweingruber FH, Harris IC and Jones PD (1999) Extracting low-frequency temperature variations from a northern tree-ring density network. In preparation.
Keith will be sending you a copy of the manuscript when it is nearer to completion.

I have also attached a PS file showing the original Briffa et al. (1998) curve, with annotation of cold years associated with known volcanic eruptions. Overlain on this, you will see a green curve. This is the new series with a 40-yr filter through it. This is just so that you can see what it should look like (**ignore the temperature scale on this figure**, since the baseline is non-standard).

With regard to the baseline, the data I've sent are calibrated over the period 1881-1960 against the instrumental Apr-Sep temperatures averaged over

all land grid boxes with observed data that are north of 20N. As such, the mean of our reconstruction over 1881-1960 matches the mean of the observed target series over the same period. Since the observed series consists of degrees C anomalies wrt to 1961-90, we say that the reconstructed series also represents degrees C anomalies wrt to 1961-90. One could, of course, shift the mean of our reconstruction so that it matched the observed series over a different period - say 1931-60 - but I don't see that this improves things. Indeed, if the non-temperature signal that causes the decline in tree-ring density begins before 1960, then a short 1931-60 period might yield a more biased result than using a longer 1881-1960 period.

If you have any queries regarding this replacement data, then please e-mail me and/or Keith.

Best regards

Tim

Calibrated against observed Apr-Sep temperature over 1881-1960
averaged over all land grid boxes north of 20N

Year Reconstructed temperature anomaly (degrees C wrt 1961-90)

Dear Mike,

I was on travel and hence the delay in responding to your email. TERI will be interested in being one of the International Supporting Institutes for the Centre. I will fax a letter to you tomorrow and send the original by post.

I have not heard on the DETR proposal as yet.

Best wishes

Sujata

Sujata Gupta, Ph.D.
Fellow and Dean
Policy Analysis Division
TERI

>>> Mike Hulme <m.hulme@uea.ac.uk> 09/28/99 02:34AM >>>

Dear Sujata,

This may well not be news to you, but the UK government has recently requested bids from UK universities to house a new 'National Climate Change Centre'. The Centre would receive funds of 2 million pounds sterling per year for (at least initially) five years. The role of the Centre would be to compliment existing work on climate modelling and data analysis (IPCC WGI areas) by focussing on 'solutions' (mitigation and adaptation options and their implementation), specifically for the UK government and business community, but within a global context. The emphasis appears to be on IPCC WG3 area with a strong commitment to integrated research, but with some overlap with WG2. The Centre would carry out independent research, but would also be expected to make use of, and to integrate, existing UK research and expertise. It would be expected to contribute to and to foster interdisciplinary research that underpins sustainable solutions to the climate change problem.

UEA is making a bid for this Centre. Applications are due by mid-October. UEA is well-known for CRU, but it also has strengths in data distribution to the climate impacts community, in impacts research, and in environmental economics (CSERGE). While these areas are fundamental foundation stones for the science that the Centre is expected to develop, the Centre would need to expand significantly beyond these areas. We have a Consortium in place as follows

- 6-7 Senior Partners - (UEA, UMIST, U.Southampton, Dept. Economics at U.Cambridge, Cranfield, Leeds Institute of Transport Studies, IH and ITE)
- Affiliated UK Organisations - (we have 6-8 of these)
- Supporting Business Links
- Supporting International Organisations

If UEA were to succeed in its bid for the Centre, then it would seek to develop strong links with other institutions abroad in order to strengthen

its own intellectual base and, through such links, to contribute to the development and implementation of the science. We would see TERI as one of these Supporting International Organisations.

To this end, we would like a short letter of support from yourself - on behalf of the Policy Analysis Division, or a wider TERI grouping if you feel able to represent them - indicating that you fully support the UEA bid and would exclusively lend your backing to this Consortium and be keen to interact closely with us at a research level were the Centre to come to UEA. This interaction may take the form of exchanging scientists, testing out new methodologies, developing/advising on workshops, providing entry-points into international policy initiatives, etc., etc.

Nothing too formal or lengthy at this stage, but we would like to provide the Council's with a flavour of the breadth of our existing and future collaboration in the field and our ability to mobilise support in our favour.

Many thanks. Please send to Prof. Trevor Davies, Dean, Environmental Sciences, UEA, Norwich, NR4 7TJ, before the 12th October.

Feel free to ask me for more details, etc. Our written text is beginning to take shape and we will circulate a draft of this to you before the bid goes in.

Regards,

Mike

p.s. I have not yet heard anything about the DETR India Programme. Have you?

Dear Mike,

I've not yet looked at your Tyndall biography, but I see your logic in suggesting his name. His 1861 papers in Phil. Mag. Ser. 4, 22, 169-194 and 273-285 were arguable the first reasonable descriptions of the CO₂ (or, in his words, "carbonic acid") greenhouse effect. However, it is generally believed that Fourier, in 1827, was the first person to allude to a greenhouse effect and to suggest that human activities might affect the climate (see, e.g., Ramanathan, Science 240, 293-299, 1988).

In my view, however, neither Tyndall nor Fourier would be appropriate for naming a climate centre devoted to human-induced change. Tyndall is not appropriate because he did not consider (or even dream of) the human influence; while Fourier is not appropriate because it would not be P.C. to name a UK centre after a Frenchman. Furthermore, both Tyndall and Fourier are well-known and well-recognized for their contributions in *other* areas.

The person who really deserves the credit is Callendar who, in 1938, not only suggested that human influences were causing CO₂ to increase, but also that this was causing global warming. Furthermore, he did an amazing job documenting both the CO₂ build up *and* the warming. Essentially, it was Callendar who, more than 60 years ago, really exposed the problem that is our current concern. His work was a quantum leap above anything done previously; and, one could argue, was not really improved upon until Manabe and Wetherald's seminal 1967 (JAS 24, 241-259) paper. I doubt whether there is an intellectual milestone in *any* field that compares with this.

Best wishes,

Tom

To: Mike Hulme <m.hulme@uea.ac.uk>
Subject: Re: apologies
Date: Fri, 8 Oct 1999 22:57:48 +0200
Reply-to: Wolfgang Cramer <Wolfgang.Cramer@pik-potsdam.de>

Dear Mike,

I can understand you very well. I would have been more nervous about this, hadn't the preparations AND registrations been going as well as they have done: just now, I feel pretty comfortable about the meeting. Sure, it's a pity not having you around, but I guess you are taking the appropriate decision under your particular circumstances.

Perhaps I shouldn't be doing this, but let me add a VERY CONFIDENTIAL piece of information for you. It won't make your life less stressful during the next few days, and I really MUST ask you to keep this confidential at your end (since I am effectively breaking a confidentiality here, and I wouldn't want Edinburgh to know that), but I received the following e-mail on October 6:

Dear Dr Cramer,

I am contacting you on behalf of Prof Paul Jarvis to check whether you are willing to have your name mentioned in association with a project he is hoping to undertake. The project is part of a much larger package of projects which forms the nucleus of a bid being made by the University of Edinburgh and other partners to host a new Climate Change Centre, to be funded by the UK Research Councils at 10 million GBP over 5 years (for further details of this opportunity see: <http://www.nerc.ac.uk/press/aoclim.html>). I work in a small unit of the University of Edinburgh that has responsibility for co-ordinating multi-disciplinary environmental research bids. Currently we are preparing the Outline Bid (deadline 15 October), so nothing should be regarded as firm, and details will be open to modification in the Full Bid, which we will prepare if the Outline Bid is successful.

Below I reproduce the text we are proposing to include in the Outline Bid. Please confirm whether or not you are willing to have your name included.

Please treat this email as confidential.

Best regards,

Simon Allen.

=====

Issue: Will terrestrial carbon sinks saturate?

It has been proposed that the assimilation of CO₂ by vegetation will reach saturation within the foreseeable future as atmospheric CO₂ concentrations continue to rise and that, conversely, increase in temperature will lead to open-ended increase in respiration by soil heterotrophs, so that at some point in the not too distant future, CO₂ efflux will come to exceed CO₂ influx.

This far-reaching assumption derives from global models that lack a consideration of acclimation, feed backs and biological constraints acting on these processes. This proposition will be critically evaluated using Dynamic Global Vegetation Models (DGVM's) that include appropriate feed backs derived from new data that are becoming available from on-going experiments in the UK and elsewhere. This core project will be executed over two years by a research fellow at the University of Edinburgh, under the supervision of Professor Paul Jarvis, FRS. The project will involve close collaboration with: the Max Planck Institut fur Biogeochemie (Prof I Colin Prentice) and the Potsdam Institute for Climate Impacts Research (Dr Wolfgang Cramer) where fully operational DGVMs are in use; the Dept of Production Ecology, University of Uppsala (Prof Sune Linder), currently conducting soil warming experiments in northern Sweden.

Costs (GBP):	Yr 1	Yr 2
Research fellow	50 k	52 k

Travel/interaction 4 k 4 k

Total project cost: 54 k 56 k

-----end of Edinburgh mail-----

To me, this comes at a very strange moment, since I am, with Bert Bolin, in a very strange situation with the completion of our second draft of the IPCC Special Report on Sinks due Land Use and Forestry. The very issue they propose to collaborate with Colin and myself about was the most contentious one of all, and Paul on one side, and several others including myself on the other side, had diametrically opposing opinions. In fact, I simply believe Jarvis either wasn't able or not wasn't willing to understand what the real issue was.

Anyway, I don't know whether, and if, in which way, this may or may not affect your completion of the UEA bid, but I thought I'd better let you know. Obviously I discussed this with Colin, and his response is that he a) would place his bet on your rather than the Edinburgh bid in terms of potential success, and b) that he nevertheless thinks Edinburgh is proposing the appropriate thing to do here, and that he therefore will reply positive to their request for collaboration. Unless you see a strong reason for recommending me to NOT do the same (we can talk about this in Brussels of course), I shall probably reply in the same positive way.

Take care,

Wolfgang

PS: I am really uncertain whether I do something terribly bad in sending this to you, after the explicit request for confidentiality - so please keep this among the two of us...

Subject: Workshop on "North-South Strategies for Sustainable Development", November 1, 1999
Date: Wed, 13 Oct 1999 15:57:37 +0530

Workshop on "North-South Strategies for Sustainable Development",
November 1, 1999

Dear Dr Hulme,

TERI is hosting an event at the Fifth Conference of the Parties on "North-South Strategies for Sustainable Development". At this event we intend to generate a discussion on the impetus for furthering the objectives of the UN Framework Convention on Climate Change. Not only is there a need to review the provisions in the Kyoto Protocol but also to develop a framework for operationalizing it. In particular, the workshop will focus on the Clean Development Mechanism. The workshop also aims to identify drivers that could maintain the momentum, which was achieved at Kyoto, ratification of the Protocol notwithstanding.

Hoping you were already at Bonn, I would like to invite you to provide your valuable viewpoint as a discussant at our event scheduled for November 1, 1999 at Hotel Maritim from 1800 - 1930 hours. A brief background note highlighting the issues intended for discussions during the Workshop as well as the Workshop agenda is attached herewith for your perusal. In case you have not planned for Bonn, I would deeply appreciate it if you could forward this mail to prospective participants to COP 5.

Thanking you and looking forward to meeting you at Bonn.

With warm regards,

R K Pachauri

Dear Dominique,

Jonathon Overpeck forwarded your email to me some time ago, regarding Holocene ice core data. I apologize for the delay in responding.

Frist, regarding US contacts for ice core data. I am happy to work on this as you suggest, and it certainly makes sense to have me involved since I have been working on ice core data management for some time. I can probably do a good job representing the US Arctic/Antarctic community, but Lonnie Thompson should also be contacted, since there is so much data from tropical glaciers that is not yet publicly available. In any case, I look forward to working with you on this.

Second, regarding ice core relevant for Holocene studies:

It would be ideal to include all of the Antarctic cores drilled so far: Dome B, Dome C, Vostok, Komsomolskaya, Byrd, etc. Much of the stable isotope data for these cores is already available at our "Ice Core Data Cooperative" web site. Valerie Masson, Jean Jouzel, myself and others recently submitted a paper comparing isotope data from all of these cores, and I should be able to get the data from her. Also at the Data Co-op site are data from the Canadian ice caps (we do not yet have Penny Ice Cap, but I can talk with David Fisher about this), Mount Logan, and from some temperate ice cores including Fremont Glacier. These data are better than commonly believed and may be useful.

I think that any Holocene climate compilation really needs chemistry and gas data as well as isotope data. Although chemical concentrations have not been measured on many of the cores, a very important data set that is missing from our current archive is the chemistry data from the Antarctic cores. All of the Taylor Dome chemistry data is available at www.sas.upenn.edu/~esteig/taylor.html but as far as I am aware there is no other chemistry data out there. It would be wonderful if you could convince Michel Legrand and colleagues to send these data to me, for inclusion on the Ice Core Data site, for both the Holocene the glacial periods.

All of the data that I currently have are available via the NOAA web server "International Ice Core Data Cooperative". The site also lists cores which exist but for which data are still needed. The direct link is:

<http://www.ngdc.noaa.gov/paleo/icecore/iicdc.html>

I apologize that the pages are not in very good order; most of my time when I had hoped to be working on this was devoted to the production of the GISP2/GRIP CDROM, which took considerably more effort than expected. I plan to begin improving those pages soon. Let me know if you have additional questions.

Warm regards,

Eric Steig

Subject: Re: CONFIDENTIAL: CRU scenarios
Date: Mon, 1 Nov 1999 14:15:36 -0700 (MST)
Cc: rwatson@worldbank.org

Dear Mike,

Thanks for your detailed response about your use of the SRES scenarios. I'm sure it will be useful to Bob Watson. I wish I could explain better what Bob's problem entails -- it is intensely political. My judgement is that, if I tell you more, then this will indirectly help Bob in answering the questions posed of him by Sensenbrenner; particularly should Bob need to get back to you. Please note that this is confidential information. Please note, too, that I am making my own judgement on this in the interest of clarifying a complex issue. I have not been authorized by Bob, or anyone associated with IPCC, to divulge this information.

The stated concern of Sensenbrenner is that the use of the SRES scenarios prior to their ratification might, in some way, jeopardize IPCC's "independence and objectivity". Sensenbrenner apparently uses as guidelines in making his judgement "IPCC's 'Principles' (as) approved in Vienna, Austria in October 1998" together with "June 11 and 28, 1999 letters" giving "Appendix A to the Principles, which is entitled 'Procedures for the Preparation, Review, Acceptance, Approval and Publication of IPCC Reports' (which was) approved ... in April 1999". Sensenbrenner implies that these documents "raise concerns about the use of preliminary IPCC material by Dr. Wigley and the Pew Center on Global Climate Change for non-IPCC purposes, apparently without IPCC sanction". He considers that "these issues (are) significant because they relate directly to the integrity of the IPCC process".

In my case, I bypassed the "IPCC process" by obtaining permission, in writing, from the 4 groups who produced the marker scenarios. I did not acknowledge the CIESIN web site. In your case, apparently, you did. The problem here is that this site stated very clearly that the data were "not for citation or quotation". Did you take notice of this?

My view is, and has always been, that contributors to such data sets or distribution sites do not give up the intellectual property rights to their own data. They could do so, of course, by signing appropriate legal/copyright documents; but I have never done this, nor, as far as I

know, has anyone who contributed to the CIESIN site. This is why I went to the individual authors in order to obtain permission to use their data in my Pew report. I hope you can see that there is an important difference between what you did and what I did. At face value, it would appear that you have ignored the clearly-stated message that the CIESIN site data were "not for citation or quotation". (More on this point below.)

You refer back to the July 1998 Bureau meeting agreeing that the preliminary SRES scenarios (in your words) "could, and should, be used by scientists". From my reading of the background material, this is subtly wrong -- the Bureau only agreed that the data could be used by "the GCM modeling community". As it happens, I am part of that community, and I acted as the interface between the scenarios and the rest of the NCAR GCM team, providing SRES data to them in a form that could be used for our GCM runs. I do not think you can claim to have filled this particular and quite specific role in your work.

However, there are some interesting subtleties here that, I think, vindicate your position. The issue is what is meant by the "GCM modeling community". In my view, anyone who uses GCM data either to provide data sets to the impacts community or to carry out diagnostic studies directly to improve GCMs is part of this community. (Note that this does **not** allow one to include the impacts modelers as part of the GCM community.) The two stated aspects are precisely what you do. Furthermore, SCENGEN (which I presume you have used in your work) makes direct use of GCMs in order to produce spatially-specific climate results based on any given emissions scenarios (including the SRES scenarios). The SCENGEN method is simply an alternative way of translating emissions scenarios into GCM-based and GCM-type output. In my view, anyone using the SRES scenarios in the development of SCENGEN, or applying SCENGEN to produce spatially-specific climate results for dissemination to others, must be included as part of the "GCM modeling community" referred to in the Bureau's agreement regarding use of the SRES scenarios. You may have interpreted the Bureau's statements even more broadly than this -- but this is of no consequence, since what you have done also falls squarely within the more restricted interpretation that I have given above.

Nevertheless, I think it would have been wiser for you to have done things the way I did, rather than to have acknowledged the CIESIN site as your source.

The next issue, raised in your email, concerns the DDC. I have not looked

at this site, but I presume it duplicates what was on the CIESIN site. If so, then its use (and the use of the preliminary SRES data) must be controlled by the rules under which the DDC was set up and operates. The key questions, therefore, are:

- (1) Do these rules allow the use of these data by anyone?
- (2) Do the SRES data, as it appears on this site, include the statement "not for citation or quotation"?
- (3) Does this make moot the whole issue of the use of the SRES scenarios?

In other words, if these data are available to all and sundry, with no restrictions, through DDC, then no one can complain about their use. (Although, in your case, since you acknowledged CIESIN rather than DDC, you may still be subject to criticism.)

What this could amount to is a loophole in the IPCC rules of procedure. Sensenbrenner might then argue that this loophole should be closed by clarifying and tightening the rules for the DDC.

The bottom line is that I think you have done things in a perfectly legitimate way. Even acknowledging the CIESIN site is legitimate, since your primary application was in the production of climate change scenarios as a member of the "GCM modeling community" as I believe this community should be defined. You have then distributed these results to the global climate impacts community who, in turn, will be feeding their results back into the IPCC process through WGII. Your chosen method of distribution (especially the WWF pathway) might be judged as less than ideal; but I cannot see anything that you have done that goes explicitly or implicitly against IPCC regulations.

Below the bottom line is the concern expressed by Sensenbrenner that these actions (yours and mine) might, in some way, have undermined the "integrity of the IPCC process". It would be interesting to hear from Sensenbrenner just how he thinks that might have happened. All we have done is distribute credible and defensible scientific information. If this information were to be in conflict with the currently best-available science, this might be an issue of concern -- but it is not. The more such credible scientific information is distributed to the community, particularly when it is presented in an easily-read, non-technical yet authoritative way, the better. I can see no way that this can distort the IPCC process. Some people, however, appear to think that it might. (A less kind interpretation might be that they are just trying to slow down the process by tying it up in legal and procedural knots -- but I have no

evidence that this is what they are trying to do.)

I hope you can see from the above quotes and somewhat convoluted arguments what a legal and political minefield this is. These sorts of issues do not seem to arise outside of the USA; but here they take on an enormous importance. One must tread very cautiously.

Cheers,

Tom

Subject: MAGICC/SCENGEN
Date: Fri Nov 12 18:19:52 1999
Cc: s.raper,m.salmon,m.hulme,barrow

Tom,

Sorry I couldn't say goodbye - I was actually on the phone to Bo Lim at the time. I also wanted to ask you about your views on the UK national climate change centre, but this can wait until later.

Anyway, about MAGICC/SCENGEN Workbook I think we agreed the following things for this UNDP version

- a select number of emissions scenarios, IS92, SRES98, 550 and 750 stabilisation cases, some Kyoto variants (perhaps from IS92a,e,d reference), and 1-2 others you may recommend. I would be keen to use your *.gas files if that's OK, even though I have some of my own. You may have done the SO2 into regions, which I haven't. Could you send me a selection?
- you would think about how to handle the CH4 adjustment to ensure SAR replicability across the emissions scenarios. This may require a tweak in the MAGICC code which Mike will have to recompile.
- we should aim to reproduce the SAR results as closely as possible in this version, e.g. use 6.37Wm⁻² rather than 5.5, and not use Prather's methane concentrations (an Annex in the Workbook will explain this).
- the variable upwelling rate will be hard-wired. Choices will remain for the Dn80s, climate sensitivity and aerosol forcing.
- SCENGEN will have the new DDC patterns included and we will switch off the buttons for the older 2xCO2 patterns.
- SCENGEN will output values over land and ocean.
- the Help Screens will need updating. I will attempt this and then check them all with you to make sure you agree.

The only problem I can foresee is that the 2.32 version that Mike and you produced in the summer corrected the aerosol calculations and also used Prather's methane concentrations. If we now want a version with correct aerosol concentrations and IPCC SAR Chapter 6 CH4 concentrations, *plus* a CH4 tweak to handle the ad hoc adjustment, then Mike Salmon will need a new and unique FORTRAN version of MAGICC. Am I right?

I have agreed with Bo Lim to get a first draft of the Workbook by 17 December, but the final version and all the CDs will not be agreed until February 2000.

Have I missed anything?

Regards,

Mike

Dear Ray, Mike and Malcolm,

Once Tim's got a diagram here we'll send that either later today or first thing tomorrow.

I've just completed Mike's Nature trick of adding in the real temps to each series for the last 20 years (ie from 1981 onwards) amd from 1961 for Keith's to hide the decline. Mike's series got the annual land and marine values while the other two got April-Sept for NH land N of 20N. The latter two are real for 1999, while the estimate for 1999 for NH combined is +0.44C wrt 61-90. The Global estimate for 1999 with data through Oct is +0.35C cf. 0.57 for 1998.

Thanks for the comments, Ray.

Cheers
Phil

Subject: A-TEAM Call is out
Date: Thu, 18 Nov 1999 14:33:21 +0100
Reply-to: Wolfgang Cramer <Wolfgang.Cramer@pik-potsdam.de>

Dear colleagues,

you may already know it: the EU FP5 second call for proposals is out since today (<http://www.cordis.lu/eesd/calls/calls.htm>), as expected, and the deadline for submission is Feb 15.

The new call does indeed answer a question I have been wondering about when I heard from many first-call projects that they were asked to re-submit. The present call is only for the slots that were, last year, declared to be opened at this stage (not for the previous slots). Probably the re-invited proposals then still bid for the old money (or at least, I hope so).

There is however one important exception: "2.3.1 Mitigation and adaptation to global change". About this, the official document says "re-open ... because of the quality of proposal received in reply to the call of 20 March 1999". Further down, they point out that Kyoto really is tremendously important for the commission ("primary objective"), and then comes the following far-reaching sentence: "If one takes into account the time lag between the research results, the political decisions and the actual emission reduction it is evident that the year 2000 is the last opportunity for research to cover the remaining analytical gaps of priority." (da_pg2_en_199902.pdf, page 6). Tough!

This mail goes to all people I have currently listed as "likely participants in A-TEAM", although the group may either grow or shrink as the remaining time passes by (depending, among other things, on your inputs!).

The present state of development is that I have recently circulated another draft of our basic document among just a few of you, hoping for input to it REALLY SOON. On the basis of this, I intend to

- a) develop a better draft that will then be circulated to all of you,
- b) organize a small brainstorming meeting, hopefully before christmas, but again only with a small core group,
- c) by christmas, provide you with a roadmap for the remaining things to be done.

Best regards,

Wolfgang

Subject: Re: industrial and commercial contacts
Date: Mon Jan 10 17:01:32 2000

Simon,

I have talked with Tim O'Riordan and others here today and Tim has a wealth of contacts he is prepared to help with. Four specific ones from Tim are:

- Charlotte Grezo, BP Fuel Options (possibly on the Assessment Panel. She is also on the ESRC Research Priorities Board), but someone Tim can easily talk with. There are others in BP Tim knows too.
- Richard Sykes, Head of Environment Division at Shell International
- Chris Laing, Managing Director, Laing Construction (also maybe someone at Bovis)
- ??, someone high-up in Unilever whose name escapes me.

And then Simon Gerrard here in our Risk Unit suggested the following personal contacts:

- ??, someone senior at AMEC Engineering in Yarmouth (involved with North Sea industry and wind energy)
- Richard Powell, Director of the East of England Development Board

You can add these to your list and I can ensure that Tim and Simon feed the right material through once finalised.

I will phone tomorrow re. the texts.

Cheers,

Mike

Hi Stepan and Eugene (Eugene are you getting these messages?)

You will have the first idea of things now and soon the first forms will come which must be filled in and signed and stamped and returned here by FAX and as soon as possible by REAL mail. The original forms must be submitted from here in February. This message is to reiterate that the reviewing process this time is going to look very carefully at the breakdown of costs in relation to precise tasks. There is even a section of the form that asks for proportional costs associated with individual deliverables. Therefore it is important to specify (at least for the sake of the plan) precisely what work can be done and the person hour costs, materials, travel, fieldwork, equipment (corers, durable equipment like computer ,GPS, etc: consumable costs like xray film etc.etc.) . I need you to think in terms of intensive sampling of modern and sub-fossil wood with the emphasis on major contributions to extending the network in Russia both ringwidth (in Ekaterinburg) and a major part of the densitometry , perhaps of Russian and non-Russian samples(?) (in Ekaterinburg). THIS IS NOT TO SAY I AM ASSUMING YOU ARE ONLY DATA PROVIDERS . I do not look on you in this way. It is simply that I have to make a strong @SPECIAL CASE@ for your both being partners and the relatively large funds that I have suggested must be convincingly justified. Your involvement is crucial on the scientific side and I will emphasise this strongly. But it is also important to display to referees what the money will go on. Hence you need to suggest various options to me in terms of possible sampling work, laboratory work and analysis and cost out these different options to cover different possible plans. We will then sort out an optimum one . You must budget realistically for travel, fieldwork travel and equipment - which I believe are expensive. Also note our earlier message as regards travel to Europe. I would very much appreciate help with up to date information on state of the art of the Russian data for background, potential of new areas or your ideas of where best to concentrate updating work.

In both Yamal and Taimyr , the continued work on the long chronologies to greatly increase sample numbers is still very high on my list of priorities and the work Stepan (and Rashit) are doing to reconstruct tree-line changes on a detailed resolution is very very important. So please try to think about the details of new sampling sites(need bigger sample numbers with different age trees at each to look at age-dependent growth changes); best areas needing updating; subfossil continuation; real numbers for different cost options and start to interact with me and Tim (and Fritz) re the possible distribution of densitometry work. Finally, Eugene, I think your comments on the ring structure and using input from simulations and model (GCM) data are important. Can we factor in some exploratory work on this or is it better to do it as part of a separate proposal - I have two more in mind in the coming months (one to NERC in UK and one to the Leverhulme Foundation - more about these later).

for now that better be all

best wishes

Keith (p.s please copy all replies to Tim)

Dear Mike

Thank you for sending the outline bid submitted last October. After reviewing the document, my colleagues and I were of the view that TERI should go non-exclusive. Our primary interest is to be part of the project and given that we (TERI) would have the role of an affiliate in both the bids, it was decided that we go non-exclusive.

We understand that the outline bid is confidential and I can assure you that it will not be shared with anyone outside the concerned colleagues at TERI. Also, I assure you of all possible support TERI can provide in developing the final bid. We look forward to a fruitful association with you on the project.

Wishing you all the best in securing the bid.

Kind regards

Sujata

>>> Mike Hulme <m.hulme@uea.ac.uk> 02/12/00 11:56PM >>>

Dear Sujata,

I attach a copy of our outline bid from last October - it is now evolving rapidly of course in preparation for final submission. This gives you a quick idea about our Consortium and plans. You will also see the names and

institutes of our partners. May I re-iterate that this document is

confidential and must not be disclosed to anyone outside your immediate colleagues in TERI.

TERI was *not* listed as a formal co-applicant (non-UK institutions are not eligible to be formal co-applicants), but was listed as an 'affiliated organisation' along with about 10 others here in the UK. We would propose to do the same in the final bid, but say a little bit more about where and how TERI would interact with us were we to win the Centre.

If you decide to remain exclusively with our bid, then I will send you the first draft of our final submission during the next week - this will indicate more details about our research programmes and where TERI may be seen to interact with us as a key overseas collaborator.

However, if you decide to join with both bids - Imperial and UEA - then we will simply continue to list you as a collaborator, but we could not then agree to any further interaction over the next 2 weeks.

Best Regards,

Mike

At 10:45 10/02/00 +0530, you wrote:

Subject: Re: BGS, Esso, & CV for Tyndall bid
Date: Thu, 24 Feb 2000 17:37:30 +0000

Mike

BGS are now on board, so please leave them in the text : I have drafted a letter for David Falvey to sign and sent it. I hope we shall get it back in time...

The Esso (Exxon-Mobil) situation is still promising, but they're having to get clearance from HQ in the USA (my best contact retired (with cancer) just a few weeks ago, so we've had to work around the new CE, to whom all this is news...). They know the deadline and will do their best for us.

Finally, my short informal CV is attached, as requested.

Hope the drafting is coming together well.

John

Hi Mike

Keith asked me to get back to you on this. The reconstruction is the same as the one I sent on the 5th October 1999, but I'm sending it again in case that e-mail isn't handy. The reconstruction has now been published, in the following paper:

Briffa K.R. (2000) Annual climate variability in the Holocene: interpreting the message of ancient trees. Quaternary Science Reviews 19, 87-105.

This paper does not, however, give full details about how the reconstruction was obtained. The details are not yet published, but will soon be submitted:

Briffa KR, Osborn TJ, Schweingruber FH, Harris IC, Jones PD, Shiyatov SG and Vaganov EA (2000) Low-frequency temperature variations from a northern tree-ring density network. In preparation (to be submitted to Journal of Geophysical Research).

Details about the file I'm sending you (repeated from 5th Oct 99):

The data are attached to this e-mail. They go from 1402 to 1994, although we usually stop the series in 1960 because of the recent non-temperature signal that is superimposed on the tree-ring data that we use. I haven't put a 40-yr smoothing through them - I thought it best if you were to do this to ensure the same filter was used for all curves. The data I've sent are calibrated over the period 1881-1960 against the instrumental Apr-Sep temperatures averaged over all land grid boxes (that have observed data) that are north of 20N. As such, the mean of our reconstruction over 1881-1960 matches the mean of the observed target series over the same period. Since the observed series consists of degrees C anomalies wrt to 1961-90, we say that the reconstructed series also represents degrees C anomalies wrt to 1961-90.

(I've already truncated the series at 1960 because of the problems with the recent period.)

Best regards

Tim

fritz.schweingruber@wsl.ch

Hi Frank

I have two names - one of which you know well. First , I strongly urge that one copy be sent to

Institute of Plant and Animal Ecology
8 Marta St., 202
Ekaterinburg, 620144, Russia

This is the home of the Laboratory of Dendrochronology , headed by Dr. Stepan G. Shiyatov and I would suggest you consign the book to him, or through him , to a genearl library if one exists.

e-mail: stepan@ipae.uran.ru
Fax: +7 (3432) 29 41 61
Phone: +7 (3432) 29 40 92

I know they have very limited resources but they will make real use of the volume . They are genuinely active and the work they do is truly 'world class'. You will remember also that one of their younger scientists (Rashit Hantemirov) won a prize in London at the Open Science meeting for his poster on the long Yamal chronology. This group gets my first and strongest vote.

My other suggestion is to send one to Eugene Vaganov's Institute of Forest.

They are not so strapped for resources as the Ekaterinburg lab. but they are large and have many active areas of research and the book would get a wide audience.

Eugene's email is
ifor@krsk.infotel.ru

Then there is the question of getting them there . The post is not reliable. You might send them to Fritz Schweingruber's laboratory from where they could be picked up or carried to Russia ?

Hope this helps
best wishes

Keith

From: Phil Jones <p.jones@uea.ac.uk>

To: Shaopeng Huang <shaopeng@geo.lsa.umich.edu>, hpollack@geo.lsa.umich.edu

Subject: Nature paper and beyond

Date: Fri, 03 Mar 2000 13:04:24 +0000

Cc: mann@multiproxy.evsc.virginia.edu, tom@ocean.tamu.edu, k.briffa@uea.ac.uk, t.osborn@uea.ac.uk

Dear Shaopeng and Henry,

First, congratulations on the Nature paper. Can you send me some reprints when you get them ?

I was at a meeting this week with Tom Crowley and we were discussing ways to reconcile the high-freq proxies with your borehole data. Here are a couple of our thoughts. Involving Mike Mann and others here in CRU, as they all have an input.

1. I've shown that the borehole data in Europe agree well with the long instrumental data in both the UK and Europe. The biggest differences/problems seem to come with the North American borehole data, which show the 16/17/18th data much cooler than the European/Asian/African data in the 16/17th century. I'm still reminded by the potential effects of land-use changes, principally in the eastern US, which could be making your North American series too cool. I realise you've taken great care with the selection, but this is a nagging doubt and will be picked up by the few skeptics trying to divide us all about the course of change over the last millennium. Is it possible to subdivide the North American borehole data into regions where we can be confident of no land-use changes (possibly and thinking aloud say Canada and the western US and Alaska) ? The aim of this (possibly joint work) is to try and reconcile the low- and high-freq proxies. Tom Crowley has a series for the NH where he's combined about 20 series (a few of which are in Mike's and the series we've produced here but he has over half the series from less-well resolved proxies - shallow marine and lake sediments) and he gets something very similar to Mike and CRU.

2. As all our (Mike, Tom and CRU) all show that the first few centuries of the millennium were cooler than the 20th century, we will come in for some flak from the skeptics saying we're wrong because everyone knows it was warmer in the Medieval period. We can show why we believe we are correct with independent data from glacial advances and even slower responding proxies, however, what are the chances of putting together a group of a very few borhole series that are deep enough to get the last 1000 years. Basically trying to head off criticisms of the IPCC chapter, but good

science in that we will be rewriting people's perceived wisdom about the course of temperature change over the past millennium. It is important as studies of the millennium will help to show that the levels of natural variability from models are reasonable. Tom has run his EBM with current best estimates of past forcing (Be-10 as a proxy for solar output and Alan Robock's ice core volcanic index) and this produces a series similar to all series of the last 1000 years.

The above is just ideas of how we, as a group, could/should try and reduce criticisms etc over the next year or so. Nothing is sacred. Your North American borehole series could be correct as it is annual and most of the high-freq proxy series respond mainly to summer variations. Is yours really annual when there is a marked seasonal snow cover season ?

Cheers
Phil

Subject: JIF news

Date: Tue, 28 Mar 2000 13:38:11 +0100

We have heard from ESRC that the ICER bid has been successful. We are to be funded at a "reduced level", although we don't know what that is yet. Our guess is that it will be close to the 10 million we were asked to approach (the revised bid was about 12.5 million).

Well done everyone.

The letter asks us not to make any public announcement, publicity or press releases until 4 April, when there will be a JIF press conference (altho we are encouraged to prepare the press as soon as possible). Please, therefore, continue to regard this information as confidential as far as the outside world is concerned - I shall ask the Press Office to do the necessary.

I will send a note out to all faculty later this afternoon.

Dear Stepan and Eugene

I was very much looking forward to seeing you both and talking over progress and future plans. I am very sorry that you were not able to attend the Mondoza meeting. I used my introductory talk for the long chronology session to illustrate the great progress and important potential of the Yamal and Taimyr work - and gave a clear indication of the quality and world significance of the continuing research at Ekaterinburg and Krasnoyarsk , and the work of Rashit and Muchtar. Please also let me apologise that Fritz may have been over zealous in requesting receipts for the small amount of money he is to forward to you. I have received these but it was not my intention that he should keep this money until the receipts were to hand. I hope no offence was taken and I am sorry that this money has not been forwarded earlier. I have asked him to send it straight away. Also I hope Stepan that you are now well. I am now back as you see and my first job is to write and send the INTAS report . I will forward copies as soon as it is complete. I have heard nothing about our proposal to the European Commission but I am not confident.

I will be sending your manuscripts back with comments in the near future for the Holocene issue.

It is my greatest hope that collaboration is continued between us even if our latest application fails and I will do my very best to find other sources of support in the future. I really want to understand more about the cell growth model and the link between long term changes in treelines and the lack of very long term evidence of climate change in our ring width and density chronologies. Please let us stay more closely in touch in the future.

my very best wishes

Keith

Christoph,

I have time for just a few brief comments. I'll leave Ed and the others to follow up if they wish...

>

Hmmm. I *think* what Ed actually meant is that if one samples e.g. only a subset of the quadrupole set of temperature "lobes" of the NAO (especially, if one samples only, say, one of them--the European one), then one will necessarily be seeing a combination of the NAO, and any other climate patterns that have a distinct regional overprint in that region. In the case of Europe, there are several. So the "nonstationarity" isn't in the *true* NAO, it is an attempt to *define* the NAO in terms of an insufficient subsample of regions influence by it.

In fact, the Cullen et al paper was originally written and submitted well before the paper you cite (GRL has an extremely fast turnaround time relative to Paleoceanography), and it wouldn't have been appropriate for Heidi Cullen to redo all the analyses using this additional index, at the time the paper was already in review/in press.

Hmmm. I'm not sure how you come to this conclusion from the results we show.

Several proxy indices are in fact quite significantly correlated (the Appenzeller index is the only one that doesn't show close correlation with the others).

>> >First, my NAO reconstruction is based on 6 North American and 4 European tree-ring chronologies. Because the putative NAO information in these records spans the North Atlantic and nicely brackets the NAO centers of action as we know them now, they potentially contain past information that is missing from a purely European-based estimate of NAO. This could occur if the NAO did not affect climate on both sides of the North Atlantic in the same roughly symmetric way back in time as it does now. If this were the case (and we have no way of knowing that now as far as I know), then it is conceivable that your L index is excessively biased towards Europe, as would be the extended Jones SLP index. If so, any comparisons between your L index and my proxy index with the Jones index would be hopelessly biased in your favor. This is not to say that my reconstruction is as good as yours, but it might not be as bad as your results indicate either.

>> >

>> >Indeed, I did make some effort to "verify" my reconstruction against early instrumental records, with somewhat contradictory and potentially interesting results. Over the 1841-1873 period, my record correlates significantly with Stykkisholmer SLP (-0.456) and Oslo temperatures (0.323), but not Bermuda SLP (0.156) and Central England temperatures (0.211). The "appearance" of significant verification with only the more northerly instrumental records may be telling us something about differences in circulation and SSTs over the North Atlantic from what is now the case. This could affect the way in which the NAO affects climate jointly over North America and Europe. Of course, when I added some earlier observations (same stations) to the verification tests (Table 4 of my paper), the results weakened considerably. So, maybe this means that my NAO reconstruction is indeed poor. However, I must admit to having doubts about the quality of the early instrumental records despite the great efforts made to homogenize and correct them. This is especially the case with regards to low-frequency variability, but can also extend to individual

Trevor

I gather you're going to collect the free lunch(?) with Esso ! I agree with Mike's analysis : i.e. there's room for some constructive dialogue...

See you on the 1014 from Ipswich (0940 from Norwich), for a kick-off at 12 noon ??

<x-flowed>

Dear Chapter 10,

Sorry I missed out on the meeting.

In general I like the proposed Figure and suggested Box contents (and I particularly agree that the diversity of downscaling methods and results precludes using them as a basis of consolidated regional conclusions). I also agree with others that it looks better with the +/- signs included. However, there are 2-3 points that concern me, mostly from the perspective of climate scenarios (Chapter 13 - and also Chapter 9).

- it needs to be made very clear if any numbers are cited in the Box (e.g. 2-6degC for continental warming) that these refer to only **one** forcing scenario, namely 1% p.a.

- rather than talk about GHG and SUL I would suggest the more conventional nomenclature of GG and GS (the SUL runs are not just SUL forcing of course, which might give that impression).

- another very important caveat concerns the GS (SUL) results - these all stem from IS92a type aerosol forcing a la IPCC SAR. Most of the new SRES forcings used in TAR and Chapter 9 for example have much smaller or even positive SO4 forcing relative to 1990. In principle this could actually switch the sign of the precip. changes in some regions. There is the danger of inconsistency here between Chapter 9 (TAR aerosol effects) and Chapter 10 Box (SAR aerosol effects) if this is not carefully explained. For example, in CAM and JJA it appears that aerosols switch the P change from 'strongly negative' to being 'uncertain' - but this is only for IS92a aerosol forcing: it is not a conclusion that would be valid for SRES aerosol forcing!

- as Filippo says, another key uncertainty not represented in the Box is forcing uncertainty - again, Chapter 9 present a wide range of Tglobal results, part of which relates to prior assumptions about which SRES forcing materialises. We do a disservice if we give the impression in Chapter 10 Box that these regional responses are independent of what future

forcing materialises. For example, under the lowest SRES forcing (B1) the precip. response in some regions would revert back to being very small and therefore indistinguishable from noise.

- with regard to temperature and Filippo's comment, Chapter 9 has global maps of T change, averaged across the standard set of AOGCM experiments (ranges are also shown). This is in effect the information being sought-for by readers of Chapter 10 is it not. I would have thought that back-references in the Box to Figure 9.9 would be sensible.

See you all in Victoria,

Mike

Dear Keith and Tim,

Thank you for the papers which I have received some days ago. They produced an impression on me. It is really a big job. I do not have time now to evaluate in details the results obtained. I want to make two remarks only.

First, I think, that the method of standardisation is very interesting, but it is disputable for the regions and sites where trees grow under extreme climatic conditions, for example at the polar timberline in Siberia. In such conditions the shape of age curve and the age of maximum growth are very changeable in different trees growing at the same site. It will be very interesting if you can present the age curve obtained for one such site, for example for the North Taymir Peninsula.

Second, I do not agree that in the northern Siberia the 15th century summers were warmer than those observed in the 20th century, at least in the Western and Middle Siberia. May be it is a result of stundartisation?

We suggest to inscribe in list of references the next papers:

1. Vaganov E.A., Shiyatov S.G., Mazepa V.S. Dendroclimatic study in Ural-Siberian Subarctic. - Novosibirsk "Nauka", Siberian Publishing Firm RAS, 1996. - 246 p. (in Russian).
2. Mazepa V.S. Influence of Precipitations on Tree-Ring Growth of Coniferous in Subarctic Regions of Eurasia //Lesovedenie, No. 6, 1999. - P.14-21. (in Russian).

Abstract. Influence of precipitation on tree-ring variability of coniferous trees in Subarctic regions of Eurasia has been shown. Depending on the region, significant ecological factor for tree growth are precipitation of autumn-winter, winter-spring and summer periods.

Ecological explanation of such influence has been given. On the base of relationships between tree-rings and rainfall the reconstructions of precipitation in different regions of Subarctic for last 200 years have been developed.

3. Mazepa V.S. Spatial Reconstruction of Summer Air Temperature in the North of the West Siberia since 1690 on the base of Tree-Ring Data.

//Siberian ecological journal, No. 2, 1999. - P.175-183. (in Russian).

Abstract. Opportunity of annual reconstruction of summer thermal conditions from Polar Urals (64-68°N, 64-68°E) up to Yenisei River (66-70°N, 86-89°E) is caused by high and sufficiently stable relationship between coniferous tree growth (*Larix sibirica*, *Picea obovata*) and corresponding climatic factors. Percent variance in tree-ring chronologies explained by climate (June-July temperature) in this extreme for growth of trees area reaches 50%. Spatial reconstruction of air summer temperature on the base of point reconstruction for 11 corresponding meteorostations has been developed. Analysis of reconstructed temperatures has shown their significant changes for last 300 years. The most strong fall of temperatures was observed in XIX century, but rise in temperature was observed in XVIII and XX centuries.

4. Mazepa V.S. Dendroclimatic reconstructing air summer temperatures since 1690 in subarctic regions of siberia. //Problems of ecological monitoring and ecosystem modelling, Volume XVII. - St.Petersburg Gidrometeoizdat, 2000. - P.170-187. (in Russian).

Abstract. The further development of many-year dendroclimatic study carried out in subarctic regions of Siberia and on the polar timberline, is given in this paper. Climatic factors determining the year-to-year and many-year tree-ring width variability were revealed, using multiple regression models. The spatial year-to-year reconstruction of air summer temperatures was made on the base of available dendroclimatic network. The reliability of spatial summer temperatures reconstruction in the boreal zone of the Urals and Siberia was evaluated. The temporal dendroclimatic zoning of the area investigated was carried out according to the chronology similarity. The regional border changes, depending on warm and cold periods, were shown. Five regional chronologies showing the nature of summer months thermic regime variability were developed. Extremely cold and warm

periods were revealed. The coldest periods are: the first half of XVII and XIX centuries. The warmest periods are: the second half of XVII, XVIII and middle of XX centuries.

To-day R. Hantemirov and A. Surkov will go to the Yamal Peninsula for subfossil wood collecting. I and V. Mazepa will go to the Polar Ural Mountains in some days.

Best regards,

Stepan

Mike

Had a very good meeting with Shell yesterday. Only a minor part of the agenda, but I expect they will accept an invitation to act as a strategic partner and will contribute to a studentship fund though under certain conditions. I now have to wait for the top-level soundings at their end after the meeting to result in a response. We, however, have to discuss asap what a strategic partnership means, what a studentship fund is, etc, etc. By email? In person?

I hear that Shell's name came up at the TC meeting. I'm ccing this to Tim who I think was involved in that discussion so all concerned know not to make an independent approach at this stage without consulting me!

I'm talking to Shell International's climate change team but this approach will do equally for the new foundation as it's only one step or so off Shell's equivalent of a board level. I do know a little about the Fdn and what kind of projects they are looking for. It could be relevant for the new building, incidentally, though opinions are mixed as to whether it's within the remit.

<x-flowed>Sorry this kept you awake...but I have also found it a rather alarming graph. First, a disclaimer/explanation.

The graph patches together 3 things: Mann et al NH mean annual temps + 2 sigma standard error for AD1000-1980, + instrumental data for 1981-1998 + IPCC ("do not quote, do not cite" projections for GLOBAL temperature for the next 100 years, relative to 1998. The range of shading represents several models of projected emissions scenarios as input to GCMs, but the GCM mean global temperature output (as I understand it) was then reproduced by Sarah Raper's energy balance model, and it is those values that are plotted. Keith pointed this out to me; I need to go back & read the IPCC TAR to understand why they did that, but it makes no difference to the first order result....neither does it matter that the projection is global rather than NH...the important point is that the range of estimates far exceeds the range estimated by Mann et al in their reconstruction. Keith also said that the Hadley Center GCM runs are being archived at CRU, so it ought to be possible to get that data and simply compute the NH variability for the projected period & add that to the figure, but it will not add much real information. However, getting such data would allow us to extract (say) a summer regional series for the Arctic and to then plot it versus the Holocene melt record from Agassiz ice cap....or....well, you can see other possibilities.

[.....At this point Keith Alverson throws up his hands in despair at the ignorance of non-model amateurs...]

But there are real questions to be asked of the paleo reconstruction. First, I should point out that we calibrated versus 1902-1980, then "verified" the approach using an independent data set for 1854-1901. The results were good, giving me confidence that if we had a comparable proxy data set for post-1980 (we don't!) our proxy-based reconstruction would capture that period well. Unfortunately, the proxy network we used has not been updated, and furthermore there are many/some/ tree ring sites where there has been a "decoupling" between the long-term relationship between climate and tree growth, so that things fall apart in recent decades....this makes it very difficult to demonstrate what I just claimed. We can only call on evidence from many other proxies for "unprecedented" states in recent years (e.g. glaciers, isotopes in tropical ice etc..). But there are (at least) two other problems -- Keith Briffa points out that the very strong trend in the 20th century calibration period accounts for much of the success of our calibration and makes it unlikely that we would be able to reconstruct such an extraordinary

period as the 1990s with much success (I may be mis-quoting him somewhat, but that is the general thrust of his criticism). Indeed, in the verification period, the biggest "miss" was an apparently very warm year in the late 19th century that we did not get right at all. This makes criticisms of the "antis" difficult to respond to (they have not yet risen to this level of sophistication, but they are "on the scent"). Furthermore, it may be that Mann et al simply don't have the long-term trend right, due to underestimation of low frequency info. in the (very few) proxies that we used. We tried to demonstrate that this was not a problem of the tree ring data we used by re-running the reconstruction with & without tree rings, and indeed the two efforts were very similar -- but we could only do this back to about 1700. Whether we have the 1000 year trend right is far less certain (& one reason why I hedge my bets on whether there were any periods in Medieval times that might have been "warm", to the irritation of my co-authors!). So, possibly if you crank up the trend over 1000 years, you find that the envelope of uncertainty is comparable with at least some of the future scenarios, which of course begs the question as to what the likely forcing was 1000 years ago. (My money is firmly on an increase in solar irradiance, based on the 10-Be data..). Another issue is whether we have estimated the totality of uncertainty in the long-term data set used -- maybe the envelope is really much larger, due to inherent characteristics of the proxy data themselves....again this would cause the past and future envelopes to overlap.

In Ch 7 we will try to discuss some of these issues, in the limited space available. Perhaps the best thing at this stage is to simply point out the inherent uncertainties and point the way towards how these uncertainties can be reduced. Malcolm & I are working with Mike Mann to do just that.

I would welcome other thoughts and comments on any of this!

Thanks Frank,

My apologies...

Sorry, no, I hadn't looked in detail at your original email to Ray, only his response, and simply wanted to note that others have already jumped on this bandwagon, so Ray deserves neither all the blame, nor all the glory, depending on your perspective :)

And, as I stated, IPCC clearly considers such a plot not appropriate for prime time--so you won't see anything like this in the TAR.

What I find most useful, however, along the lines of what you discuss, is using empirical reconstructions as a baseline for comparison against model simulations of both free and forced variability. A number of studies have attempted this recently, and the results are encouraging from the point of view that (a) the coupled models appear to be getting the internal variability of mean global/hemispheric temperatures about right [this leads us in the direction of having greater faith in future scenarios from such models] and (b) the models, forced with paleoestimates of past volcanic, solar, and GHG radiative forcings, appear to be able to explain more than 50% of the variance in the paleo temperature reconstructions. A paper to appear in this Friday's "Science" by Tom Crowley describes some impressive results along these lines.

It is agreed that hydrological change and regional temperature anomalies superimposed on any large-scale temperature changes are of key importance from any practical point of view. And I think this is what we're all working towards, more regionally detailed reconstructions of climate fields (temperature, drought, slp, etc.) in past centuries. Clearly more high-resolution proxy evidence is necessary, in both time and space. I make many of these very points in a "Perspectives" article also to appear in Science on Friday, accompanying Tom Crowley's article.

Will appreciate any comments on it. Hope the above provides some clarification.

cheers,

mike

Keith

I've sent you a few slides taken by Hakan Grudd as promised . I think these should be supplemented by a bit of a colourful timeseries - part of a chronology. It could be a piece of the Tornetrask series (northern Sweden) from where the pictures are taken - but I think a section of the 3-region average (Tornetrask, Yamal, Taimyr) possibly showing the 563 A.D. would be better. So I am sending a couple post script files and a suggested colour scheme. What do you think? I suggest a one hundred year section of the average series , showing annual values. Note that in these Figures , A.D. 536 is marked by a filled triange. Just showing the initiation of a dramatic cooling in A.D. 536 and the widespread cold summers of the 540's (a major vocano? if perhaps not as David Keys makes out in his recent book), or a comet (as Mike Baille says in his?) , is quite appealing.

Subject: Re: climate reconstructions

Date: Fri Aug 4 15:10:06 2000

Dear Fortunat

I am pleased to hear from you. I have still not been in touch about the data I showed you in Vienna! As for your question - of course I will send the series you mention - but it is only an average of three regional tree-ring chronologies (Northern Sweden, Yamal,Taimyr) and not calibrated in terms of temperature. Nevertheless, it is representative of summer warmth over a large Russian region, We have recently submitted a paper describing a different standardization approach (for preserving low frequency variance) applied to a big high-latitude network of tree-density data. This yields regional (up to 600-year) calibrated reconstructions and a hemispheric curve - all representing april-sept season. I have asked my colleague Tim Osborn here to send the data and a copy of the papers to you, I am on the verge of leaving for 2 weeks so if you need more information contact him. As for other areas of the world - Phil Jones has an alternative Hemisphere curve and there are some southern hemisphere chronologies (temp. sensitive). There are short precip reconstructions for several spots - but systematic Palmer Drought Indices for the U.S. from about 1700. I will be happy to talk on the phone about all these in two weeks.

best wishes

Keith

At 11:01 AM 7/19/00 +0200, you wrote:

Dear Keith,

How are you? Hope everything is going well.

I am writing because I am interested in your climate reconstruction for the last millennium.

The Etheridge ice core data of CO2 indicate that CO2 was below average in the 17th and 18th centuries by a few ppm. Very few (1-2 points) of ice core C13 data (Francey tellus, 99) suggest that this drawdown was caused by additional terrestrial carbon storage (Joos et al, GRL, 99; Trudinger, Tellus, 99). We try to investigate this suggestion using the Lund-Potsdam-Jena dynamical global vegetation model (LPJ-DGVM).

A diploma student of mine, Philippe Bruegger, has used the Mann et al annual mean temperature patterns (2 EOFs only) in combination with the Etheridge CO2 record to drive the LPJ model. Instead of absorbing carbon, the model is releasing carbon due to a reduced CO2 fertilization effect in the model that outweighs any climatic effects. Thus, the model results is clearly not compatible with the ice core results.

Obviously, the study is hampered by the limitation of the climate reconstruction (as well as by the few C13 ice core data). Instead of

changes in monthly values of Temp and precip (and cloud cover) changes in ANNUAL mean temperature were used to force LPJ.

Could you or Phil Jones provide alternative forcing fields that focus e.g. more on summer temperature? Any info about precipitation?

I would also appreciate very much to obtain reprints of your most recent articles, namely the article in Quaternary Science Rev. 2000.

Thanks for any help you can provide.

Regards, Fortunat

Tom and Mike,

What Tom said is essentially correct. Tim Osborn here recalibrated each series, as a composite, against the same NH series for the April-Sept average north of 20N (using land only data). All this does is rescale the series as it is simple regression ($y=ax+b$). Because y is based on temps wrt 61-90 this means that the axis is then wrt 61-90. Doing this we can then add the same instrumental temp series. It also brings the series together and the web page was just for illustrative purposes. For Mike's series you get pretty much the same result by subtracting 0.12 from Mike's numbers as this is the difference between Mike's base period and 1961-90.

There is nothing sinister going on ! I'll summarise this to Rob.

Cheers
Phil

PS I seem to be stirring up loads of emails about historical data. You are both on those emails so you can see what crap is being written and my (time wasting for me) replies. Apologies for replying. I should know better and keep quiet. We can all expect more of this if IPCC stays in roughly the same form pre-Victoria. It's relatively easy to knock historical records, so as long as it gets no worse than this we'll be fine.

<x-flowed>Dear Ray

You sent me this op-ed (?) (Letter to editor?) about the need to convert the US from a carbon-based economy to a hydrogen-based economy. I can't guess why you wanted me to know your views, but it does help me to better understand what motivates your scientific work and judgment. It also throws some doubt about your impartiality in promoting the "hockey stick" temperature curve that a number of us have been critical of.

In any case, I doubt if espousal of this energy policy will help BP and ARCO discover a source of hydrogen somewhere.

You quote the "progressive" Business Council approvingly: "We accept the views of most scientists that enough is known about the science and environmental impacts of climate change for us to take actions to address its consequences." And from BP chairman : "the time to consider the policy dimensions of policy change is not when the link between greenhouse gases and climate change is conclusively proven, but when the possibility cannot be discounted and is taken seriously by the society of which we are part."

I note that BP and ARCO are still out there exploring for oil; they don't seem to be quite ready yet to put real money where their mouth is.

You call for the US to take leadership in stabilizing the climate. Perhaps the government will turn to you to learn how to do this. A far less ambitious goal would be to stabilize the atmospheric concentration of CO2. According to the IPCC this would require an emission reduction of 60 to 80 percent (with respect to 1990) --- WORLDWIDE.

Have you ever considered the consequences of such a policy -- assuming it could really be adopted?

Best wishes ,

Fred

Cc: jfbmitchell@meto.gov.uk,k.briffa@uea.ac.uk

Chris and John (and Mike for info),

I'm basically reiterating Mike's email. There seem to be two lots of suggestions doing the rounds. Both are basically groundless.

1. Recent paleo doesn't show warming.

This basically stems back to Keith Briffa's paper in Nature in 1998 (Vol 391, pp678-682). In this it was shown that northern boreal forest conifers don't pick up all the observed warming since about the late 1950s. It was suggested that some other factor or a combination of factors related to human-induced pollution (e.g. nitrogen deposition, higher levels of CO₂, ozone depletion etc). Hence in a new paper submitted to JGR recently we develop a new standardization approach (called age banding) and produce a large-scale reconstruction (calibrated over the period 1881-1960 against NH land north of 20N) back to 1402. If you want a copy of this can you email Keith and he'll send copies once he's back from holiday.

This background is to illustrate how Singer et al distort things. The new reconstruction only runs to 1960 as did earlier ones based solely on tree-ring density. All the other long series (Mike's, Tom Crowley's and mine) include other proxy information (ice cores, corals, historical records, sediments and early instrumental records as well as tree-ring width data, which are only marginally affected). All these series end around 1980 or in the early 1980s. We don't have paleo data for much of the last 20 years. It would require tremendous effort and resources to update a lot of the paleo series because they were collected during the 1970s/early 1980s.

It is possible to add the instrumental series on from about 1980 (Mike sought of did this in his Nature article to say 1998 was the warmest of the millennium - and I did something similar in Rev. Geophys.) but there is no way Singer can say the proxy data doesn't record the last 20 years of warming, as we don't have enough of the proxy series after about 1980.

<http://www.co2.science.org/edit/editor.html> takes the argument further saying that as trees don't see all the warming since about 1960 the instrumental records recently must be in error (i.e. this group believes the trees and not the instrumental records). This piece by Idso and Idso seems to want to have the argument whichever suits them.

2. Everyone knows it was cooler during the Little Ice Age and warmer in the Medieval Warm Period.

All of the millennial-long reconstructions show these features, but they are just less pronounced than people believed in the 1960s and 1970s, when there was much less paleo data and its spatial extent was limited to the eastern US/N.Atlantic/European and Far East areas. The issue seems to revolve around the average temperatures we have for earlier centuries in the millennium. I use the argument that for the instrumental period we need sites located over much of the NH (land and marine) regions in order to claim we have a reasonable record for the whole hemisphere. We wouldn't dream of extending the NH series based on longer European records and in the extreme just CET, so with the paleo data we need records from as many regions as possible. The coverage still could be better, but it is far better than it was 25 years ago, when the ideas embodied in the MWP and LIA became sort of mainstream.

The typical comments I've heard, generally relate to the MWP, and say that crops and vines were grown further north than they are now (the vines grown in York in Viking times etc). Similarly, statements about frost fairs and freezing of the Baltic so armies could cross etc. Frost fairs on the Thames in London occurred more readily because the tidal limit was at the old London Bridge (the 5ft weir under it). The bridge was rebuilt around the 1840s and the frost fairs stopped. If statements continue to be based on historical accounts they will be easy to knock down with all the usual phrases such as the need for contemporary sources, reliable chroniclers and annalists, who witnessed the events rather than through hearsay. As you all know various people in CRU (maybe less so now) have considerable experience in dealing with this type of data. Christian Pfister also has a lifetime of experience of this. There is a paper coming out from the CRU conference with a reconstruction of summer and winter temps for Holland back to about AD 800, which shows the 20th century warmer than all others. Evidence is sparser before 1400 but the workers at KNMI (Aryan van Engelen et al.) take all this into account.

I hope this is of use and hasn't been a total waste of time.

In Victoria last month, did you discuss how the policymaker's summary will report the millennial temperature series ? Are there any tentative phrases you're working on a la Balance of evidence etc ? Is Chapter 12 thinking of a new sentence to supercede the above ? Any sentence on the millennium record should be in Ch. 2.

Cheers
Phil

To: Benjamin Santer <e782144@popgun.llnl.gov>
Subject: JGR paper
Date: Fri Aug 18 17:19:46 2000

Ben,

Here a few main points about the paper. I've ignored minor English/wording things I spotted.

p4 It seems better to put the other anthro forcings before the natural get discussed. (top of page). ie Other heteorogeneous.. sentence should be before Stratospheric aerosols.

p4 Bottom. Could reference Delworth et al to illustrate the 'perfect' model argument. They reproduced reality 1 out of 5 attempts.

p5 Don't like phenomenology of ENSO, change to ENSO sequences ?

p6 middle. Emphasise that withe models you can look at a lot longer series.

p6 bottom. Whether the model was really 'perfect' Michaels would find some problem.

p7 2/3rd way down. Say something about Santer et al (2000a).

p9 Don't think you need to say you got the SOI from CRU.

p10 ECHAM4 has solar, but how much does it change by. Or is it constant ?

p11 end of 2. Presumably in combining the SAT and SST you used anomalies. Worthwhile saying.

p12-15 Section 3 gets to read like a recipe. It is important, but it might be better as an Appendix. Also I guess the amount of detail depends on success of other submissions. I think the section needs reworking a bit as the style changes somewhat.

Have you considered whether alpha and tau and t(ramp) can differ by a month between the surface and 2LT.

The lag you use is 7 months. The science paper of Tom's uses 6 months.

In the later tables I wasn't clear how raw and nofilt relate to each other. I guess all the Tables need longer captions with more explanation. I couldn't figure out what the () numbers referred to in the Tables.

p17 I wonder if it's possible to show in a diagram that the iterative scheme works and you're getting to a global rather local minimum.

p19 The higher 'ratios' get nearer to my 2, but only at the high end.

p20 The last 4 numbers in Table 3 have been multiplied by 0.1 .

p23 An interesting aside would be to show in one of the Tables how much change in the observations is due to volcanoes (ie show how much cooling due to this there has been). People will quote this value. It shows that 'natural' factors (solar/volcanoes) have led to cooling as solar effects will be very small over this time.

p24 Emphasise later that models and obs all show 2LT level changes more than surface.

p24 Say something about how good ECHAM4 is for ENSO, or refer to a paper.

p25-33 All good stuff, but it does take a time to read. Not a very helpful comment, I know, but I'm being a referee.

p33 Does Fig 7 use the same data as in Fig 5 ? One showing things through time, the other as a distribution.

p35 PCM crept into the Hamburg section, so it should be said here when the GISS section starts.

p38 Quantify the volcanic cooling. I mentioned this earlier.

p39 Not clear what independent components are wrt Smith et al (2000).

p42 Surface data has errors too.

p43 The last sentence of the acknowledgements is like a red rag to a bull for Michaels. Even the perceptive adjective will not placate him.

Have to go home now. I think I've covered most things I noticed.

Have a good weekend !

Cheers

Phil

Great Tom, I think we are converging to much clearer meanings across various cultures here. Please get the inconclusive out! By the way, "possible" still has some logical issues as it is true for very large or very small probabilities in principle, but if you define it clearly it is probably OK--but "quite possible" conveys medium confidence better--but then why not use medium confidence, as the 3 rounds of review over the guidance paper concluded after going through exactly the kinds of discussions were having now. Thanks, Steve

Subject: Re: cool bristlecone, etc

Date: Fri Aug 25 15:19:20 2000

Hi again Malcolm

I am forwarding the data in another message (from Tim). I am sending the whole lot for simplicity. Please don't pass on until we hear whether the paper is accepted or not.

Remember that , although they are strongly correlated with them, these data are not identical in the high frequency domain to the equivalent data standardised using say a Hegershoff function. The main purpose here was to extract long-timescale variations and I still consider the inter annual to decadal variability to be better defined using the 'traditional' approach. For a first look anyway these are fine

best wishes

Keith

At 04:14 AM 8/24/00 -0700, you wrote:

Dear Keith,

It was good to talk with you this morning. This is a reminder about sending your Western North America banded record as you suggested. I suspect that you are right to think that it would eventually be best to use a customized banded set, but as a start, I think it would be good to compare the WNW record with the mean series Graybill and Idso used in their 1993 paper, and with the single site Campito Mountain record. I'll start with a simple graphical comparison and then move to comparing waveforms extracted by, for example, SSA. My hope is that we can fairly rapidly generate a note to something like GRL or JoC's new short format, putting a believable version of these records out there for general use.

Please reply to the mhughes@ltrr.arizona.edu address. I'm sending it from my other address as well as a 'belt-and-braces' approach because of recent e-mail problems. Looking forward to working on this with you, Cheers, Malcolm

Subject: Re: interactive climate science-policy website,
Date: Tue, 5 Sep 2000 00:14:56 +0100
Reply-to: "Ben Matthews" <ben@chooseclimate.org>

Dear Mike,

Regarding my last message,

In case you wonder about my background, I have attached a 2-page version of my CV, in rich-text format, file bjhmcv2.rtf

My experience, ranging from laboratory work with CO₂ fluxes and marine algae, through to organising events at the UN climate negotiations, combined with a strong mathematical and linguistic background, is a somewhat unusual combination which perhaps makes me more a "jack of all trades" than a specialist. On the other hand, this has given me an interdisciplinary overview which may be valuable for bridging the gap between science and policy, appreciating dilemmas and uncertainties, and communicating these around the world.

However, Kyoto left me very disillusioned by the apparent lack of connection between climate science and policy -in the protocol there was not one sentence discussing what we need to do to stabilise the climate in the long term, based on scientific predictions. This made me wonder, what is the use of my intricate research on air-sea CO₂ exchange, if the policymakers ignore even the most basic knowledge? I left UEA and started working at home, developing interactive web graphics showing the link between per-capita emissions and global climate change. Eventually, I realised that working alone was neither effective nor sustainable, and this has led to unfortunate personal circumstances. Now I need the stimulus of working again in a team, in an institute, even if this requires sacrificing of my own ideas. I am not just looking for a "job", it is more important to me, to rejoin the research community, and feel I am making the best use of my skills. I hope you can help, if only to discuss the possibilities.

I have also attached a zip package containing the interactive java applets which I developed,
it's only 90K including supporting webpages and historical data.
Once unzipped (all in one directory), you have to open the file "starthere.html" in any java-enabled web browser.

I can send a self-extracting windows version if you prefer, on the other hand you may find it easier just to look at the website

www.chooseclimate.org/applet/

Currently, this uses only very crude formulae loosely based on IPCC SAR and GCI's C&C, -but the presentation is unique: you can adjust the parameters just by dragging controls with a mouse, and all the linked plots respond instantly. It's hard to describe in words, which is why I encourage you to have a look.

Ben

Dear Mike

I have attached the final version of the RP2 outline proposal on the interaction between the flexible mechanisms and the WTO trade rules. Please jettison the previous draft.

As noted earlier, Neil and I see this project as delivering multiple benefits to the Tyndall Centre on the basis of a limited, 'value-added' investment, not least in terms of tying Shell International to the Centre. We also highlight the suggestion of a workshop on common themes to be held in a couple of years' time to link related projects across the research programmes (though this is not covered by the current proposal).

Dear CLAs/LAs

As you all know, in my Victoria follow-up e-mail of 2 August I presented a summary of the agreement we reached in Victoria on a common use of terminology to express degree of likelihood in the TAR. At that time the word or term to be used for the central box of 33 to 66% had not been agreed and the word "inconclusive" was proposed for that category. Since that time there has been a lengthy discussion, including Working Groups II and III, regarding the best word to be used in this category. To cut a long story short the term we would now like you to use for this middle category is "medium likelihood". I am sorry I have not been able to canvas this around all of you but from the discussions this term was agreed by all to be the best compromise. In particular, it clearly maintains the scale as one of degrees of likelihood, whereas inconclusive could be confused as to whether a degree of likelihood was being expressed or whether there was insufficient information to conclude a likelihood. I attach a table showing what should now be the final scale.

During the discussions it became clear that in addition to making likelihood statements it is sometimes more appropriate to express statements in terms of a degree of confidence, and indeed several chapters use this terminology. As you know the Uncertainties Guidance paper by Richard Moss and Steve Schneider recommends a scale of confidence from Very Low to Very High confidence. WGII in particular are using this scale and so I would ask that, if you choose to express things in terms of a level of confidence, that you use the terms as they are laid down in the guidance paper. This in no way affects the use of the likelihood scale where this is more appropriate. For

example, if we are highly uncertain how well a model handles a particular process, we may have "very low confidence" in a model result which is highly dependent on this process. If we have no other corroborating evidence we may therefore conclude that there is insufficient information to assign a likelihood in this case. By following the guidance paper when expressing a level of confidence we will hopefully improve the consistency between the two reports. Incidentally, if there are instances in the WGII report where they are able express degrees of likelihood they are going to try and use our scale.

Thirdly, there has been a lot of discussion about the impression which the likelihood scale, if taken out of context, could give for low likelihood, high consequence events, such as a disintegration of the WAIS or a shutdown of the THC in the next 100years. Please bear in mind that policymakers must balance likelihood and consequence in deciding whether or not to take action. Therefore please take extra care when considering text for these types of issues as simply expressing them as "extremely unlikely" does not give the full picture. For example, you could say an aircraft was "extremely unlikely" to crash on its next flight but if there was a 1% chance I would not fly on it. While it is a true statement the right balance is only achieved when the consequence is also brought in to put the risk in context.

I apologise for this late change to our scale but I hope you all agree that it is an improvement. If anything is not clear about any of the above please do not hesitate to contact me.

Best regards

Dave

Date: Mon, 11 Sep 2000 16:58:02 +0200 (MET DST)

Dear All

we heard the opinions of most LAs, namely Jens, Richard, Linda, Peter, and Hans as well as some interesting interpretations of my email (Linda says:

" You seem to be assuming that the most desirable result is if the SRES results have no contrasts with the IS92a results. I don't understand your reasoning on this." I do not have any particular desire on the new data. We said that one thing to look at was the agreement with the old data and thus I noticed that relaxing the criteria would yield a greater agreement). I would say that a broad range of opinions was covered, from one where the SRES should essentially be commented upon concerning their agreement with the old data to one in which all the old stuff should be replaced with SRES stuff. Some people want to make the BOX more central, others want to get rid of it.

Given this, I would like to add my own opinion developed through the weekend.

First let me say that in general, as my own opinion, I feel rather uncomfortable about using not only unpublished but also un reviewed material as the backbone of our conclusions (or any conclusions). I realize that chapter 9 is including SRES stuff, and thus we can and need to do that too, but the fact is that in doing so the rules of IPCC have been softened to the point that in this way the IPCC is not any more an assessment of published science (which is its proclaimed goal) but production of results. The softened condition that the models themselves have to be published does not even apply because the Japanese model for example is very different from the published one which gave results not even close to the actual outlier version (in the old dataset the CCC model was the outlier). Essentially, I feel that at this point there are very little rules and almost anything goes. I think this will set a dangerous precedent which might mine the IPCC credibility, and I am a bit uncomfortable that now nearly everybody seems to think that it is just ok to do this. Anyways, this is only my opinion for what it is worth.

Going to the problem at hand, I have a proposal that is in between the two extreme positions. I think the SRES runs should be included and highlighted in the chapter, but should not be the only source of our conclusions, partially also for the reasons I state above (I seem to remember that in Chapter 9 the SRES results were only a small section in the whole chapter in which it was said that they essentially confirmed previous findings). Also let me say that, as it currently stands, the box is essentially meaningless, because it simply repeats what is already said in the executive summary. With these premises here is my proposal:

1) We leave 10.3 more or less as it is, a discussion of published science on model behavior, uncertainty, some climate change runs. Perhaps we shorten it or something like that. I am not in favor of presenting Giorgi and Francisco-type plots for the SRES runs for the simple reason that they do not convey effectively what readers want. Proof is that we had all the plots there and we were accused of not having any results in the chapter !! I think people want something more direct, i.e. plots similar to the +/- one we had proposed in the BOX.

2) We make the BOX only with SRES results, i.e. the BOX becomes a summary presentation of the SRES projections. In this way we accomplish several objectives: we highlight the SRES results in a way that is of direct impact (after all this is what working group II people are really interested in); we can explicitly state that the results are preliminary and sort of differentiate them from the more IPCC-proper chapter material (of course we are not going to say so); we have a natural place for the BOX (end of 10.3), do not need to rewrite the whole thing and just need to make the proper connections with the rest of the chapter. All and all I think this is a feasible and clean solution. The rest of the material in the old box (sections a and c) was really just general material repetitive of what we were saying in various other part of the chapter.

3) In the executive summary we summarize what we believe are the confident patterns from the combination of old and new runs.

As to what should the SRES box look like. I hear people liked a lot our +/- plot, so we do the same types of plots, both for precip and temperature, one for the A2 and one for B2 scenarios, plus one or two paragraphs explaining the plots. This will portray agreement not only across models but also across what are now considered plausible scenarios. We can easily fit 4 plots in a page and if need be fit the 1-2 paragraphs on another page (I do not see anything wrong with a 1.5 page box). For precipitation I think the old criteria are fine. For temperature this

is what I propose. In the precip plots we had 4 sub-categories, (+, - large change, small change) plus the inconclusive, or whatever we decided to call it. Similarly, we could do 4 categories here
1) Amplification positive, 2) Amplification negative (i.e. less than the global average), 3) strong amplification (> 50%), 4) small amplification (between 25 and 50 %). I cannot visualize it at the moment, but I think this will work to figures analogous to the precip ones. Correct me if I am wrong.

To the two technical issues:

1) Do we soften our requirement, i.e. from n-1 to n-2 model agreement? I do not feel strongly about it but am more in favor of not softening the criterion. We are looking for confidence and model agreement and should have stringent requirements on it.

2) Do we include the outliers in the analysis? I say yes, not having time for more detailed analysis as to why they should not be included. In Chapter 9 they are presented as bracketing the answers not as being wrong.

This is the problem of not having published research on this. perhaps a paper would have excluded them on scientific grounds, but can we at this point? I am not sure we can have solid enough foundations to legitimate it. Besides, I have done analysis without them as well and things did not change almost at all.

To the operational issues:

1) I agree there is no time for a paper to be delivered before the Sept. 26 deadline. After the deadline however, and with some calm, I think we should have a paper on it.

2) Meeting or conference call. I myself am not keen on a meeting of the Europeans. Jens is not back until the end of the week, which means the meeting would have to be during the last week before deadline. With all that is still left to do on the chapter and other internal commitments I have,

I certainly could do without spending 2 days to do this (which is always the minimum it takes me to get anywhere and back)and I cannot do it over the weekend since I am not here.

It sounds like we would have to contact people by phone anyways (see Peter and Linda's messages), so why not a conference call directly?

>From the technical viewpoint Linda seems to be the best person to organize this. As soon as Jens is back perhaps? (Jens if you can read this

can you let us know when this is possible?).

3) We just got the MPI data and the full CCC ones (I guess some was lost in the previous run). We need to incorporate these so we have all models available. I and Bruce will interact on this.

4) I agree we should contact the TSU about it, but I also think we should have a proposal on it with less spread than current to present them.

Last but not least, please work on your section revisions (especially those who have nothing to do with the BOX) so at least we get that out of the way.

Cheers, Filippo

Subject: more on "what to do"
Date: Tue, 12 Sep 2000 11:53:20 +0200 (MET DST)

Dear All

I think I heard replies to my last proposal from most of you. I have also had a phone conversation with Linda. So let me try to summarize the situation

1) From the replies I got, it sounds like at least the basic idea of my proposal is viable. In particular I read an at least semi-consensus, and certainly some strong individual positions, that the SRES material , since it is unpublished (and remember unreviewed until now), should not be presented as our sole or even primary source of conclusions. Now, I share that position and in fact quite strongly. Presenting such material breaks the proclaimed IPCC rules. Now the rules have been softened for this case, but remember that there are people around who are paid to find faults in the IPCC process and the last thing I want to do is being accused of having broken the rules. I think the TSU people are too optimistic and casual in the way they change the rules during the process and expect people to accept that this "just" happens. Remember what happened to Ben Santer after the SAR. Besides, I myself think that material for a document as important as the TAR cannot be drawn from last-minute barely quality checked and un-peered reviewed material (people have barely looked at the MPI run that was completed last friday !!). It is up to the IPCC to better plan these things and avoid the mess. Be it as it may, unless somebody is strongly against this position, I will assume that we can proceed from this basis.

2) Having said the above, it is also clear that we can present the IPCC data in some format. Chapter 9 is doing it (remember also in their case the SRES stuff is only a minor component of the chapter) so we can and I think we should because it is relevant and important material, but with the proper caveats clearly up front, i.e. that whatever we present is a preliminary analysis that has not undergone a publication process. It would be certainly strange and confusing to have the SRES discussed in Chapter 9 but not in our chapter in some form. Besides we went through a significant effort to get it and process it. I myself think that the SRES information is important to provide. It is just unfortunate, but not surprising, that it came around too late.

3) So the question is at this point how do we present the SRES. I suggested not to incorporate it within the text of 10.3, since 10.3 is our assessment of published research which has undergone peer and government review. I stand strongly by that suggestion. Obviously 10.3 might need a bit of rewriting to make it flow better with possibly different conclusions but not more than that. I then suggested to make the Box an SRES Box including the +/- format figures (I thought we needed 4, i.e. two for each scenario, but Linda pointed out we really need only 2, one for precip and one for temperature each including the two scenarios). Now this offers several advantages: we can say right up front that this is from a preliminary analysis; we can separate it cleanly from the rest of the "official " text; it gives direct info in a format that people seem to like. Two very legitimate comments were made on this. Peter said, if we give this more palatable format (the +/- figures) only for SRES data would it not implicitly give it too much attention? Linda said: why not present similar plots for the IS92 data? The obvious action which would address both of these concerns is to present similar plots for the IS92 data. This is certainly an option. The only problem I see is that I think the clear separation of published and unpublished results would be lost if we put it in the BOX. The alternative is to do those figures and put them in 10.3, leaving the SRES for the BOX. This could be a good option, although it might require significant effort. All and all, I am still in favor of an SRES-only box with a clear statement up front that gets us off the hook in case of problems (you can see it as a sort of disclaimer I guess).

So let's come to the next point: we need to decide on this and soon. The best way appears to be a conference call. Linda suggested thursday, which is fine with me. It now looks like Richard cannot organize this. So Linda I am afraid you are left with the organization of it. The call would have to be during European-South African afternoon - US morning and I am afraid I am not sure what time in Australia. problems is: Jens can you make it? I think Jens is the person in the group most strongly opposed to presenting SRES data, so it important he is in the conference call. It is also critical that Peter participates, given he has been the main player in all this. Now here is my proposal:

Conference call on thursday 3 p.m. Trieste-Hamburg time, which means 4 p.m. Cape town time, 2 p.m. Bracknell time, 9 a.m. Boulder time, 8 a.m. Fairbanks time and ??? Australia time. Linda is this feasible for you to organize? Is this ok for all? Conbin, are you available at all?

items of discussion:

Question 1): Do we do an SRES BOX with +/- figures?

Question 2): What are the technical details (n-1 vs. n-2 model agreement, inclusion of outliers, threshold for large vs. small vs. no change both for precip change and temperature amplification factor).

Question 3): Do we do similar figures for IS92 data which would either replace the current figures on IS92 in the text (I think this would be perfectly acceptable since it is simply a way to present in a different way published results).

Question 4): How do we incorporate the SRES results within the current executive summary

I hope that by thursday I will have all data to do all relevant figures. I need to get CCC control and MPI-DMI data from Bruce and dig out the old IS92 data. If not by thursday then hopefully by friday. Once I have the data I can easily directly calculate all the thresholds necessary for doing the relevant figures. I will then circulate all the material to you.

Needless to say that any data based on SRES that is circulated among us should NOT go any further (except for the chapter of course) until we decide what to do with it (a paper or something like that).

In the mean time, I will never tire to keep asking you to please work on the section revisions and let's get those out of the way.

Cheers, Filippo

Subject: RE: n-1 / n-2
Date: Thu, 14 Sep 2000 10:30:27 +1100

Dear all,

It could be viewed that using n-1 for 9 models where we used n-1 for five
models before is an implicit change in the stringency of our criterion.
When we had five models, agreement (0/5, 1/5, 4/5 or 5/5) could be
expected
37% of the time just by chance (ignoring the near zero case). With nine
models the equivalent figure for n-1 is only 3.5%, and it is still much
lower for n-2 (18%)... (assuming that my somewhat rusty probability
calculations are correct). It really depends on what we had understood
the
purpose of the criterion to be. I am not certain how much this was
discussed.

Also, I would prefer Friday night as well if it means that more
information
will be available.

Cheers

Peter

Subject: n-1 / n-2

Dear friends,

I have already indicated that I favour the n-1 version. Obviously, this
choice is arbitrary, but it was made BEFORE we did the analysis. By
changing the criterion AFTER we have seen the data, we may be targeted
by critics for biased rules. Using material, which is unpublished and
unreviewed is already a bit shabby (Hans Oerlemans is unwilling to
participate in the IPCC process because of a similar incident in the
1995 report!).

Hans

Warwick,

I did not think I would get a chance today to look at the web page. I see what boxes you are referring to. The interpolation procedure cannot produce larger anomalies than neighbours (larger values in a single month). If you have found any of these I will investigate. If you are talking about larger trends then that is a different matter. Trends say in Fig 2.9 for the 1976-99 period require 16 years to have data and at least 10 months in each year. It is conceivable that at there are 24 years in this period that missing values in some boxes influence trend calculation.

I would expect this to be random across the globe.

Cheers
Phil

Warwick,

Been away. Just checked my program and the interpolation shouldn't produce larger anomalies than the neighbouring cells. So can you send me the cells, months and year of the two cells you've found ? If I have this I can check to see what has happened and answer (1).

As for (2) and (3) we compared all stations with neighbours and these two stations did not have problems when the work was done (around 1985/6).

I am not around much for the next 3 weeks but will be here most of this week and will try to answer (1) if I get more details. If you have the names of stations that you've compared Olenek and Verhojansk with I would appreciate that.

Cheers
Phil

Cc: <k.briffa@uea.ac.uk>

Dear Tom,

The difference between the Campito Mountain record and, for example, the one from the Polar Urals that you mention, is that there is no meaningful correlation between the Campito record and local temperature, whereas there is a strong correlation in the Polar Urals case. I give references to the work reporting this phenomenon at the end of this message, but I'm afraid I'm missing the references to the technical comments that are being responded to in the last two. If you examine my Fig 1 closely you will see that the Campito record and Keith's reconstruction from wood density are extraordinarily similar until 1850. After that they differ not only in the lack of long-term trend in Keith's record, but in every other respect - the decadal-scale correlation breaks down. I tried to imply in my e-mail, but will now say it directly, that although a direct carbon dioxide effect is still the best candidate to explain this effect, it is far from proven. In any case, the relevant point is that there is no meaningful correlation with local temperature. Not all high-elevation tree-ring records from the West that might reflect temperature show this upward trend. It is only clear in the driest parts (western) of the region (the Great Basin), above about 3150 meters elevation, in trees old enough (>~800 years) to have lost most of their bark - 'stripbark' trees. As luck would have it, these are precisely the trees that give the chance to build temperature records for most of the Holocene. I am confident that, before AD1850, they do contain a record of decadal-scale growth season temperature variability. I am equally confident that, after that date, they are recording something else. I'm split between Harvard Forest and UMASS these days, and my copy of your paper is not with me today. I'd be interested to know what the name of the site for the LaMarche central Colorado record was.

Cheers, Malcolm

Subject: Status of our JGR paper

Date: Fri, 22 Sep 2000 12:36:38 -0700

Dear All,

I just wanted to keep you informed about the status of our draft JGR paper. First, thanks to all of you for your comments - they were very helpful. I am now in the process of revising the paper, and hope to have a new draft ready by Oct. 10th. After several discussions with Tom, I have decided to repeat the volcano/ENSO signal separation for the observed data and for the GSOP experiment.

The reason for this is that there was a conceptual flaw in what I had done previously. The flaw related to the determination of the "pre-eruption" reference temperature, used as a baseline for estimating the maximum volcanically-induced cooling. Let's call this baseline temperature "TBASE". Previously, I was estimating TBASE for Pinatubo and El Chichon from either the raw or Gauss-filtered temperature data at time $t=0$ (the eruption month). If I was calculating TBASE from the filtered data, the estimate of TBASE was biased by "contamination" from post-eruption cooling. In other words, since I was using a 13-term Gaussian filter, temperature values from $t=0 + 6$ months were influencing TBASE, likely leading to an underestimate of the true TBASE value. I've now modified the program so that TBASE is not computed from the filtered data; instead, it is an average of the temperature anomalies in the MREF months prior to the eruption. There is some sensitivity to the choice of MREF (I've been experiment with values ranging from 6-18 months), which again underscores the uncertainties inherent in separating ENSO and volcanic signals.

The maximum volcanically-induced cooling is still estimated using filtered data, but now I'm using a 5-term binomial filter rather than the 13-term Gaussian.

These changes require repeating most of the analyses in the paper. Preliminary results indicate that the revised estimation of TBASE increases the ratio of the Chichon/Pinatubo maximum coolings, and brings this closer to the ratio of the Chichon/Pinatubo radiative forcings.

Tom has also made a number of useful suggestions regarding reorganization and shortening of various sections of the manuscript. Hopefully the next iteration will be a little shorter than the current version of the paper!

I will be out of my office next week, but should be back by October 2nd.

With best regards, and thanks again for all your help,

Ben

Ben (or, really, everybody else),

I don't know whether you have all seen the paper analyzing the observed data that Ben and I sent to J. Climate ?? This is where the JGR paper began, and it is useful to compare both papers. In the J. Climate paper we assessed the best fits using a subjective balance of raw and lowpass filtered results. The reason for this was because of the difficulty of setting up an automated procedure -- which is the problem that Ben is currently having to deal with. In the next iteration of the JGR paper, the reason for moving to a more automated procedure will be explained. Both the subjective and automated procedures have their advantages and disadvantages. The latter procedure, of course, is in no way 'objective'. Many subjective choices have to be made in setting up the procedure. This is why the word 'automated' is used above, rather than 'objective'.

If you have not seen the J. Climate paper, let me know and I will send you a copy. There is a companion paper that has been accepted by GRL that I will send at the same time.

Cheers, Tom.

Dear Mike

I know Tim has communicated with you about plans for his visit to Virginia. We have discussed ideas here and I ,for one, am excited about the prospects of joint work. Thank you for agreeing to his visit and for taking the trouble to arrange things .

The purpose of this brief message is simply to reiterate what we said in our brief discussions in Venice - namely that it is our intention to work with you rather than in any sense of competition. Our motivation for wanting to do some of the detailed comparisons between the results of our work and your own is to understand the sources of uncertainty in both. We are also committed to doing some of this work by the terms of our current NERC grant. We wish to involve you as much as possible , get your advice , and solicit criticisms of our approach -especially in relation to the Palaeo-model comparisons .

Our EC proposal was not funded , but we wish to follow it up with another to PRESCIENT (a NERC Thematic Programme of research along the same lines), and again we would be happy to collaborate with you. Better two way communication between here and there would be a major help.

It is my feeling that the relatively short time Tim has with you , might be best spent getting to grips with the finer details of your "old" and "new" approaches, including the details and results of your other work that is only partly described in the publications (seasonal runs, different data sets etc.) and , most importantly, discussing approaches and philosophies for data-model comparison work. That way he could come away with some concrete plans , and the means of fulfilling them, on his return. Any time you can spare to discuss and liaise along these lines would be much appreciated. He has discussed the specifics of your suggestions and I am happy with the approach and prioritization he has expressed.

While he is with you , we can always exchange emails if any issues need wider discussion.

very best wishes

Keith

Hi Keith et al,

Thanks for your message.

This sounds fine. I do have to warn that with a full teaching courseload this semester, my own free time will necessarily be somewhat limited. Thus, Scott's involvement here will be key.

Scott has been dealing w/ the new methodology and analyses, and hence my concern w/ any plans that expect new analyses w/ our old methodology. The code is not especially user friendly, though Tim is welcome to use it. Scott will be able to devote a decent share of his time to these activities during Tim's visit, though this will necessarily have to be split with time devoted to activities that Scott is explicitly supported for by our NOAA grant (ie, the development of a synthetic proxy network from model data, and wavelet-based calibration methods, as detailed in my previous email).

So I'm sure we'll be able to find common ground. Tim will have free access to our data and codes, and can make the comparisons indicated below. We of course appreciate your willingness to make available to us the tree ring density data.

It may be interesting to do a (highly preliminary!) analysis of both proxy datasets with our expectation maximization ridge regression scheme, and that would certainly fit in well w/ both our agendas (your NERC grant, and our NOAA grant).

Hopefully, our 4-processor Dell server (running Linux) will be back up and running, so Scott can use our Sun server, while Tim will have the Dell server to himself if he needs it.

I hope the above all sounds good.

Best regards,

mike

Dear all

Here's another MWE reference, originally announced by the Idso's. I
looked up the abstract from the South African Journal of Science and
here's its URL

http://www.gheiss.de/Personal/Abstracts/SAJS2000_Abstr.html

That puts the MWE and LIA into South Africa.

Cheers

John D.

Myles and Curt,

Attached are the NH and SH averages from the new variance corrected analyses (HadCRUTv). When the paper comes out in JGR (probably early next year) you'll see that variance correction is only possible from 1870.

So in these files I've patched on the 1856-1869 data on the front so they are the same length. This early data is the same as the original version (HadCRUT). For the global series I still think the best way of producing this is by averaging the two hemispheres. HadCRUT is what you all probably have - it is on the CRU web page. Again I would produce the globe by averaging the hemispheres so what Chris Folland has for the globe may differ slightly as the HadC produce this as one domain.

The way the variance correction is achieved is by reducing the high-freq variance of each grid-box series. This means that when I update the series for 2000 some values for the last few years (1995-9) will be altered slightly.

I don't know much about Chapter 2, but I don't recollect there being any power spectrum diagrams. Probably left for the detection chapter. Do make sure the axes and units are well explained. Don't leave anything for the skeptics to cling to !

Cheers
Phil

To: stepan@ipae.uran.ru,eavaganov@forest.akadem.ru
Subject: intas
Date: Fri Oct 6 10:30:24 2000

Stepan and Eugene

I have asked INTAS for an extension on the report period. Stepan some problem has now arisen regarding your final payment . I have asked Janet to sort this out and contact you directly.

I have to give an up to date report on chronology development and tree-line changes at the PAGES meeting in Avignon on October 24-26 and I would really appreciate some Figures that demonstrate the latest state-of-the-art in the Yamal and Taimyr (and any other good Russian evidence) . The focus of the meeting is High-resolution variability of the Holocene , and the long records and evidence of tree-line changes is particularly valuable. Later there will be some large review papers (with many authors) summarising the information from high latitudes, mid latitudes, the tropics etc. The form of these papers is not yet decided but you would be contributing authors. I am also (with Ray Bradley,Julie Cole and Malcolm Hughes) writing a Chapter on the last 10000 years (with a major emphasis on the last 1000) for the PAGES Synthesis book and I intend to include a summary Figure that includes your work - I hope this is O.K Malcolm has just asked for a letter of support from me for a project he is submitting to NSF , in which I believe you are both involved. I have sent it to him. I am still exploring when we can resubmit our own proposal to the EC, and I will write an application to The Leverhulme trust before the end of this year. I am still discussing the Holocene ADVANCE-10K issue and I will be in touch about your papers.

best wishes

Keith

To: Keith Briffa <k.briffa@uea.ac.uk>
Subject: Yamal treeline figures
Date: Mon, 9 Oct 2000 18:08:04 +0500
Reply-to: Rashit Hantemirov <rashit@ipae.uran.ru>

Dear Keith,

Stepan Shiyatov tell me that you need some figures concerning Yamal chronology and tree line dynamics to show somewhere in France.

Attached are archived files contained some figures.

File MAP - the map of region of research. Red dots - subfossil wood sites, green marks - recent northern border of larch along river valleys.

File FIGURES - in Excel format, contains several figures.

Sheet "Values-10" - data on northernmost position of trees and number of trees dated for corresponding year (decadal step)

Sheet "Treeline" - dynamics of treeline in Yamal during last 7000 years reconstructed using about 1000 subfossil wood remains. Recent treeline position is about 67°34'.

One year ago we supposed (C-14 data, Hantemirov, Shiyatov 1999) that significant drop of treeline (the transition from "middle" to "late" Holocene) was about 1700-1600 AD. According new data it was earlier (about 2550 BC). May be it is because of lack of data from region northward of 68°N (only 25 datings)?

Sheet "Treeline and Nu" - treeline dynamics and number of dated trees. May be number of trees reflects the long scale climate fluctuations as well.

Sheet "2600-all" - for last 4600 years: treeline dynamics, number of trees, 11 most cold summers for last 7000 years (according our version of reconstruction), most expressed frosts in July (reconstructed using junipers from Polar Urals, see file PATHOL, frost in 1626 BC - based on subfossil larch - you can put away it), summer temperatures reconstruction smoothed with 20- and 100-year filters (our version of reconstruction).

Sheet "Values-2" - values for preceding figures, in 2-years

step.

Sheet "Yam-Ur-fig" - comparing of treeline data for Yamal and Polar Urals upper treeline dynamics (data by S.G.Shiyatov)

Sheet "Yamal-Ural" - values for preceding figure, in 2-years step.

Sheet "Treeline-std" - treeline dynamics and 50-year standard deviations of summer temperatures (our version of reconstruction). This figure shows surprising high negative correlation. However may be both of them just reflect long scale climate fluctuations?

Sheet "Std" - 50-year standard deviations of summer temperatures (our version of reconstruction) .

File PATHOL - in Excel format, contains data and figure on pathological structures in tree rings of Siberian juniper (*Juniperus sibirica* Burgsd.). According our data (Hantemirov et al., 2000) the presence of frost rings provides evidence for frosts that occurred in late June or first days of July (frost rings in earlywood) and in the first half of July (frost rings in late wood). Long term and pronounced temperature drop in the middle of very warm period in the second half of July is the factor responsible for wood density fluctuations (false rings).

Please let me know when you receive this. Some time large messages get lost.

P.S. We (Eugene Vaganov, Stepan Shiyatov, Leonid Agafonov and I) will be in Birmensdorf from 23 till 29 October. Are you going to Switzerland after your meeting? We would be happy to see you there.

Subject: Re: JGR paper
Date: Thu Oct 19 17:55:41 2000

I am just having to go so I will think about the "should we?" . The answer to the "can we?" is yes. I have spoken to the person organising the editorial review and she has promised me she will get it to us in the next week or so. If we can get it back immediattely she says we can make the December issue. Therefore it is possible to do the edits if it means very little change to the text. I have also confirmed that we will pay 1500 dollars for the colour and they say they are working on these now. I really want to get this into the 2000 so I can include it in the RAE. Ed is here now and has some great looking extended PDSI reconstructions (1000 years) for the western US.

I am suspicious as to whether the negative trend in Mike's Hockey stick prior to the 20th century is not at least partly the result of a trend in the long high elevation western US trees he uses . Malcolm sent me some figures for the HIHOL meeting and in this work he cuts off the juvenile growth sections of the long tree data but does no detrending on the remainder. This might leave a linear age trend in these data. I remember that Mike in his long reconstruction , stated that the pc representing the western US stuff was essential for getting a verifiable result. Interesting , but only a diversion. We can discuss the JGR and other stuff in Avignon. Hope your weekend was a god one. I tend to agree a bout the NAO meeting- you could use the money (and perhaps time) to better effect.
At 04:24 PM 10/19/00 +0100, you wrote:

Keith,

have you had to produce the camera-ready copy for the age-banded JGR paper yet? If not, then is it possible to make some minor changes to it? For the comparison with the Mann et al. reconstruction, I had previously just taken their land&marine full northern hemisphere mean annual temperature time series and re-calibrated it against the instrumental land north of 20N Apr-Sep mean temperature time series. Well, I have not taken the Mann et al. spatial temperature field reconstructions, and computed a land north of 20N area mean.

I still have to re-calibrate it against the instrumental series because it is an annual rather than Apr-Sep mean. After doing all this, you'll be pleased to know that the final figure is only slightly different (the Mann et al. curve is very slightly more of an outlier during the 1500-1700 period, and is cooler and closer to observations post-1950, but not much different elsewhere). What does change, however, are the correlations. The correlations with instrumental data are slightly worse (from 0.76 to 0.73, and from 0.92 to 0.89 decadal), but I'm not sure that we show these anyway. But the cross-correlations between the Mann et al. and the other reconstructions (which we do show) are all stronger than previously - which now seems a little

unfair on them.

Cross-correlations between unfiltered series:

Mann versus: Jones, Briffa (ABD), Briffa (Torn+Tai+Yam)

before: 0.47, 0.36, 0.33

now: 0.50, 0.37, 0.34

Cross-correlations between 50-yr smoothed series:

Mann versus: Jones, Briffa (ABD), Briffa (T+T+Y), Overpeck, Crowley

before: 0.78, 0.43, 0.50, 0.86, 0.76

now: 0.81, 0.51, 0.55, 0.86, 0.78

I don't have a copy of the paper in front of me, but the 'before' values should match those in one of the tables. Some of the 50-yr smoothed new values are noticeably stronger.

Can we make these changes still, or is it too late? And do you think we should?

Cheers

Tim

To: Ben Santer <santer1@llnl.gov>
Subject: Re: Figures for revised version of paper
Date: Wed Oct 25 14:38:07 2000

Ben,

I hope the surgery next week goes OK. Ruth and I are going away next week for a short break to Coldstream on the River Tweed. This was the holiday cottage Matthew had planned to go to for his honeymoon, but the fuel crisis around his wedding time precluded this. We were able to negotiate the cottage for a later date, as we could get a refund or claim on the insurance as a national emergency wasn't declared. So on Nov 1 we will think about you !

I've listed off the diagrams and will take the text when it comes, but I won't be able to send you any comments until the week of Nov 6.

Also just sent back comments to Mike Mann on the paper by Tom and you factoring out ENSO and Volcanoes. Felt like writing red ink all over it, but sent back a short publish subject to minor revision to Mike. This is the first time I've ever reviewed one of Tom's or your papers !

Copy of what I sent is attached. I forgot to sign it before sending it !

Again hope all is well later next week !

Cheers
Phil

Internet: [1]http://www.auto.com/industry/iwirc26_20001026.htm

LONDON -- BP Amoco Plc, the world's No. 3 publicly traded oil company, and Ford Motor Co. said they will give Princeton University \$20 million over 10 years to study ways to reduce carbon-dioxide emissions from fossil fuels. BP said it will give \$15 million. Ford, the world's second-biggest automaker, is donating \$5 million. The gift is part of a partnership between the companies aimed at addressing concerns about climate change.

Carbon dioxide is the most common of the greenhouse gases believed to contribute to global warming.

London-based BP said it plans to give \$85 million in the next decade to universities in the U.S. and U.K. to study environmental and energy issues. In the past two years, the company has pledged \$40 million to Cambridge University, \$20 million to the University

of California at Berkeley and \$10 million to the University of Colorado at Boulder.

Hi Jap

please see the following - I have had the data put on my web site and I will slowly put other data and Figures and Abstracts on there also. Let me know if you have a problem downloading the data. Good luck

Keith

The data you want are included in those listed under -

XXVI General Assembly, Spring EGS Meeting

Comparison of Large-Scale Proxy-Based Temperature Reconstructions Over the Past Few Centuries

MANN, M.E.; RUTHERFORD, S; OSBORN, T.J.

OA28.0 Study of past climates: Climate of the past millennium

JOUZEL, J.; (co-conveners: JONES, P.D.; MANN, M.E.)

Comparison of Large-Scale Proxy-Based Temperature Reconstructions Over the Past Few Centuries

M.E. Mann(1), S. Rutherford(1), and T.J. Osborn(2)

(1) Univ. of Virginia, USA, (2) Climate Research Unit, Univ. East Anglia, UK

A promising approach to the problem of reconstructing patterns of past climate variability

involves the application of spatial climate field reconstruction (CFR)

techniques to networks of proxy

climate indicators (e.g., Mann et al 1998;2000--see

http://www.ngdc.noaa.gov/paleo/ei/ei_cover.html).

This approach seeks to exploit the complimentary information in a diverse

network of proxy indicators by determining the most consistent relationships between these networks of data and the leading spatial patterns of climate variability during a recent "calibration" period of overlap with the modern instrumental record. The calibrated relationship is then used to estimate large-scale patterns of climate variability in the past from the proxy data. This method makes no assumptions regarding the relationship between a given proxy indicator and specific local annual/seasonal climate variable, but does assume that the proxy indicator is tied to some combination of large-scale patterns of climate variability. Alternatively, it is possible to estimate large-scale temperature patterns from a relatively homogenous network of proxy climate indicators (e.g., tree-ring density data--see Briffa et al, 1998) by invoking a local calibration between each climate indicator and the climate variable (e.g., summer temperature) of interest. This approach is more conservative in the amount of information it seeks to extract from the proxy data network, but it is free from assumptions regarding the large-scale patterns of past climate variability. Recent reconstructions of Northern Hemisphere annual-mean and warm-season temperature patterns using these respective approaches and data show some similarities, but also some important differences. Here we investigate these differences more closely, examining the sensitivity of Northern Hemisphere temperature pattern reconstructions to (a) the underlying proxy data used, (b) the particular method used to estimate large-scale patterns from these data, and (c) the target seasonality of the reconstruction. By controlling independently for each of these three factors, we gain insight into the reasons for differences between various proxy-based estimates of past large-scale temperature variability.

Dear Colleagues

At the HIHOL meeting in Avignon in October, several of us (Steig, van Ommen, Dahl-Jensen, Vimeux) agreed to write a review paper addressing Holocene climate change as viewed from polar ice core records. The main task of writing and organizing this paper has fallen upon Tas and Eric, and

we are writing to solicit your interest, support, and contribution. We would appreciate hearing from each of you with comments on our proposed plan, requests for clarification and (hopefully) data sets. We hope you will be interested in working with us on this project. Note that the deadline for completion is the end of March, 2001.

Although the question of Holocene climate change has obviously been addressed in numerous papers on individual ice core records (and most recently in the Masson et al. review of Antarctic records in QR), we believe that it would be valuable to select the best-understood, best dated, polar ice core data from both hemispheres and put them in a single paper. We also think that the paper should be limited only to

1) data that address directly the TEMPERATURE history at high latitudes -
-
the information
we get from isotopes and from borehole reconstructions -- as opposed e.g. to atmospheric circulation changes that one gets from the chemistry record,
and

2) discussion of the long-term variations, as opposed to short term variations such as the Little Ice Age.

The intention here is not to be exclusive of either people or ideas, but to limit the scope of the paper so that it is as definitive a document as possible. Of particular interest is the "simple" question of the timing and magnitude of the "thermal maximum", the subsequent Holocene cooling, and their relationship to insolation forcing. This was a major question at the HIHOL meeting and we do not believe it was adequately resolved there.

Our vision is a summary paper that not only reproduces already-published

work, but that carefully quantifies the uncertainties inherent in each of the reconstructions. Of particular interest are the possible effects of elevation change on the records, and uncertainties in the timescales. We cannot say a priori what the conclusions of this paper will be. An example might be that the "thermal maximum" was actually warmer than present - a major issue of contention in the popular literature - and was more-or-less simultaneous in both polar regions. If this is correct, it will be a useful service to the paleoclimate community to demonstrate it. Alternatively, we may find after carefully looking at the data that we CANNOT reach such a conclusion. This would be an equally important result.

How should we proceed? Our suggestion is that those who are willing to participate send their favorite ice-core based temperature reconstructions to us, providing the best available timescales and a brief description of the uncertainties you ascribe to the reconstruction. We will compile the data and produce both 1) a single file containing all the data, and 2) a PDF figure comparing all the independent temperature reconstructions. We can then initiate discussion around a common figure, so that everyone is looking at exactly the same information. The last 11,000 years would be considered the appropriate time interval to consider. We do not wish to confuse matters by including the glacial-interglacial transition!

Data sets that we think would be particularly important include the following. Note that we will probably need to include other authors. This is just a preliminary list and is not intended to exclude anyone. We are also aware that some of these data are so far unpublished but we hope that they could be included anyway, perhaps in "smoothed" form (?).

- 1) Isotope profiles from Vostok, Byrd (and EPICA, if possible), on the most-accepted timescales (Francoise).
- 2) Isotope profiles from Taylor Dome and Siple Dome, Dye 3 and GISP2 (Eric).
- 3) Isotope profile from Dome Fuji (Fujii)
- 3) Isotope profiles and borehole temperatures from Law Dome core(s) (Tas, Vin).*
- 4) Isotope data from GRIP (and from N-GRIP if possible) (Dorthe)
- 4) Borehole data from Taylor Dome, GISP2, Dye 3 (Gary, Ed).*
- 5) Borehole data from GRIP (and N-GRIP if possible) (Dorethe)
- 6) Isotope, meltlayer frequency, and borehole T data from the Canadian ice caps (David, Fritz)
- 7) Meltlayer data from other sites (GISP2 - Alley?)

*The Law and Taylor Dome records only go to mid Holocene but would still be very useful here!

Other suggestions for data sets and people to contact?

Again, please reply to this email with your comments, criticisms concerns, request for clarification and (hopefully) data sets!

Thanks!

Warm regards to all,

Eric Steig & Tas van Ommen

<masson@lsce.saclay.cea.fr>

Valerie, Françoise et al.

We also were surprised by the "conclusion" that there was a 9-7 ka optimum. This probably arose from a statement by Greg Zielinski regarding the Arctic records. In any case, the article by Dominique and Kieth was just a rough draft -- we have pointed out the mistake to them and I expect we will all see a final version anyway!

Regarding the subject of the HIHOL paper, we agree that there are already many papers published that discuss the temperature interpretation of isotopic records during the Holocene. What has not been done, however, is to include the best Holocene records from both polar regions in a single paper, nor to make a specific comparison of the timing and magnitude of the optimum (or optima). For example, the elevation effect on the long-term trends for East Antarctica has been discussed (Masson et al., 2000) but not quantified. Of course quantifying this effect is difficult but our paper could put useful error estimates, for example, on the amount of cooling in the late Holocene. We do not of course wish to compete with Sigfus, but his paper will be more limited in geographic focus than ours and will include new data that we will not use. It would be good to include NGRIP borehole temperatures if we can, but this is not necessary. Even the GRIP and GISP2 records show very clearly the Holocene optimum. Our suggestion would be to let Dorethe decide on that, in consultation with Sigfus.

In our vision, one of the key features of the Holocene article will be its deliberately limited scope and confinement to observation rather than speculation about causes of climate change. We think that to involve modelers and oceanographers makes it difficult to keep the focus and is rather beyond the intended purposes of the Holocene volume. Keep in mind that modelling was looked at separately at the HIHOL meeting and we believe that the modelers at the meeting are planning their own contribution to the

volume.

As mentioned earlier, we think the best way to get the paper going is to begin soon the process of simply collating data sets and putting them all on one graph. We can then discuss the details of the paper with the same image in front of each of us.

We hope that you can agree more-or-less with the above, and that others on our email list will also provide some input. We are of course open to further discussion!

Further comments?

Dear friends of the ECF,

Attached I send you:

- An executive summary of the ECF (to be revised anytime on the basis of your suggestions),
- The current version of the ECF "Manifesto" (to be revised anytime on the basis),
- The minutes of the Amsterdam preparatory meeting of last November.

We do have an URL by now: <www.European-Climate-Forum.net>. We will gradually develop it, please feel free to make suggestions. We also have an internal section, see: <www.European-Climate-Forum.net/internal/>.

Her at PIK, Dr. Martin Welp will take care of ECF logistics for the time being. His e-mail address is: Martin.Welp@pik-potsdam.de.

As for the Logo search, I like these things very much, although I am really not knowledgeable at all. We might make a pre-selection and run a competition on our web-site, inviting cyber-visitors to give their opinion

- we will still be free to choose what we like best. Perhaps rather than looking for the single best Logo right now it is more fruitful to identify which proposals find enough appreciation to become part of the web competition.

And let us enjoy these more playful moments without neglecting the key challenge we are faced with: Defining first joint projects and reaching agreements with relevant stakeholders to actually carry them out.

As for the foundation technicalities, we are preparing a background document that we will send out soon.

A final remark on e-mail etiquette: Could we put the string "ECF" in the subject line of all e-mails dealing with ECF, in order to enable our various browser to filter these pearls out of the ocean of e-mails we have begun to live in?

Best regards,
Carlo Jaeger
and Martin Welp

> Science Reviews, 19 (2000) 87-105. It should deal with many of the
> questions people raise about using them to determine temperatures.

Take this from first principles.

A tree only grows on land. That excludes 70% of the earth covered by water. A tree does not grow on ice. A tree does not grow in a desert. A tree does not grow on grassland-savannahs. A tree does not grow in alpine areas. A tree does not grow in the tundra

We are left with perhaps 15% of the planet upon which forests grow/grew. That does not make any studies from tree rings global, or even hemispheric.

The width and density of tree rings is dependent upon the following variables which cannot be reliably separated from each other.

sunlight - if the sun varies, the ring will vary. But not at night of course.

cloudiness - more clouds, less sun, less ring.

pests/disease - a caterpillar or locust plague will reduce photosynthesis

access to sunlight - competition within a forest can disadvantage or advantage some trees.

moisture/rainfall - a key variable. Trees do not prosper in a drought even if there's a heat wave.

snow packing in spring around the base of the trees retards growth temperature - finally!

The tree ring is a composite of all these variables, not merely of temperature. Therefore on the 15% of the planet covered by trees, their rings do not and cannot accurately record temperature in isolation from the other environmental variables.

In my article on Greening Earth Society on the Hockey Stick, I point to other evidence which contradicts Mann's theory. The Idso's have produced more of that evidence, and a new article on Greening Earth has 'unearthed' even more.

Mann's theory simply does not stack up. But that was not the key issue. Anyone can put up a dud theory from time to time. What is at issue is the uncritical zeal with which the industry siezed on the theory before its scientific value had been properly tested. In one go, they tossed aside dozens of studies which confirmed the existence of the MWE and LIA as global events, and all on the basis of tree rings - a proxy which has all the deficiencies I have stated above.

The worst thing I can say about any paper such as his is that it is 'bad science'. Legal restraint prevents me going further. But in his case, only those restraints prevent me going *much* further.

Cheers

John Daly

Dear Phil,

Thanks for your response. I agree that I think these folks just don't quite seem to get it! Anyways, I've pasted in the text of Broecker's piece below (everything there but the figure. Trust me, the figure isn't worth looking at anyways). Will be very interested to hear your thoughts after reading this...

mike

PALEOCLIMATE:

Was the Medieval Warm Period Global?

Wallace S. Broecker*

The reconstruction of global temperatures during the last millennium can provide important clues for how climate may change in the future. A recent, widely cited reconstruction (1) leaves the impression that the 20th century warming was unique during the last millennium. It shows no hint of the Medieval Warm Period (from around 800 to 1200 A.D.) during which the Vikings colonized Greenland (2), suggesting that this warm event was regional rather than global. It also remains unclear why just at the dawn of the Industrial Revolution and before the emission of substantial amounts of anthropogenic greenhouse gases, Earth's temperature began to rise steeply.

Was it a coincidence? I do not think so. Rather, I suspect that the post-1860 natural warming was the most recent in a series of similar warmings spaced at roughly 1500-year intervals throughout the present interglacial, the Holocene. Bond et al. have argued, on the basis of the ratio of iron-stained to clean grains in ice-rafted debris in North Atlantic sediments, that climatic conditions have oscillated steadily over the past 100,000 years (3), with an average period close to 1500 years. They also find evidence for the Little Ice Age (from about 1350 to 1860) (3). I agree with the authors

that the swing from the

Medieval Warm Period to the Little Ice Age was the penultimate of these oscillations and will try to make the case that the Medieval Warm Period was global rather than regional.

One difficulty encountered when trying to reconstruct Holocene temperature fluctuations is that they were probably less than 1°C. In my estimation, at least for time scales greater than a century or two, only two proxies can yield temperatures that are accurate to 0.5°C: the reconstruction of temperatures from the elevation of mountain snowlines and borehole thermometry. Tree ring records are useful for measuring temperature fluctuations over short time periods but cannot pick up long-term trends because there is no way to establish the long-term evolution in ring thickness were temperatures to have remained constant. Corals also are not accurate enough, especially because few records extend back a thousand years. The accuracy of the temperature estimates based on floral or faunal remains from lake and bog sediments is likely no better than $\pm 1.3^\circ\text{C}$ (4) and hence not sufficiently sensitive for Holocene thermometry.

The Mountain Glaciation Record

At the Last Glacial Maximum, mountain snowlines throughout the world were on average about 900 m lower than today (5). On the basis of today's rates of temperature change with elevation, this required an air temperature cooling at the elevation of the glacier of about 5°C (and a corresponding tropical sea surface temperature cooling of about 3°C). During the Younger Dryas--a cold "spell" of about 1200 years during the last deglaciation--snowlines in the Swiss and New Zealand Alps dropped to about 300 m below the lowest levels reached in the subsequent Holocene.

Since their 1860 maximum at the end of the Little Ice Age, the retreat of Swiss glaciers represents a rise in snowline of about 90 m (6). If this rise could be attributed entirely to air temperature, the required warming would be between 0.5° and 0.6°C. However, simple considerations suggest that precipitation changes result in a negative feedback of about 20% (7). The warming required to account for the post-1860 retreat of Alpine snowlines would then be between 0.6° and 0.7°C.

The post-1860 glacier retreat is not confined to Switzerland. With the exception of Antarctica, it has been well documented everywhere on Earth where ice-covered mountains are present (2). There is no doubt that the Little Ice Age was global in extent and that the post-1860 warming was also global. In this regard, the Mann et al. (1) reconstruction is consistent with the mountain snowline record.

The Medieval Warm Period has also left its traces in the Swiss Alps.

Holzhauser has reconstructed the history of a larchwood aqueduct constructed by medieval farmers (8). It ran from a small mountain lake along the valley occupied by the Grosser Aletsch Glacier, supplying water to an Alpine village. The aqueduct was first constructed around 1200 A.D. (toward the end of the Medieval Warm Period). It was partially destroyed when the glacier advanced in 1240 A.D. and had to be totally rerouted after a further advance in 1370 A.D.

Swiss geologists and geomorphologists agree that the large moraines marking the maximum glacier extent during the Little Ice Age are a composite of debris left behind by a series of Holocene advances (9). For example, soils separating individual advance episodes have been found within the moraines. Precise dating has proven difficult, however, and the chronology of these prior advances remains uncertain.

Two recent studies of Holocene climate cycles in the Swiss Alps have greatly improved this situation. Both focus on establishing the times of glacial retreats rather than advances. Holzhauser (8), on the basis of radiocarbon dating of larchwood stumps exposed by the ongoing retreat of the Grosser Aletsch Glacier, finds warm episodes 2400 ± 300 and 1500 ± 200 calendar years ago. Hormes and Schlüchter (10-12) have dated wood and peat fragments that are being disgorged from beneath a number of Swiss glaciers. Radiocarbon dates of a large number of these samples cluster in three major groups centered at 8700, 6600, and 4300 calendar years before present. The correlation between these Alpine warm phases and the warm phases of Bond's North Atlantic ice-rafting record, although imperfect, is encouraging (see the figure).

Climatic oscillations during the Holocene. Circles show the ratios of iron-stained to total grains (for grains with diameters $>63 \mu\text{m}$) in a North Atlantic core (3). The chronology is taken from (22). The green (10-12) and yellow (8) boxes are based on radiocarbon dating on wood and peat formed when the glaciers had retreated to positions similar to or up-valley from those at present (see text).

Borehole Thermometry

Geothermal heat is produced deep inside Earth, and the shape of the vertical temperature profile measured in a borehole from any point on Earth's surface thus reflects the depth dependence of the thermal conductivity of the crustal material. The temperature at the surface does not remain constant, however, and the thermal profiles therefore have kinks that reflect past air temperature fluctuations. Mathematical

deconvolutions are used to reconstruct these fluctuations from the temperature profile, but because of smoothing due to diffusive spreading of past thermal anomalies, many different time histories fit the observed downhole temperature record. The modeler selects from these possibilities the temperature history with the least complicated shape. The details are thus lost, and only the broad features of the time history are captured.

Deconvolutions of thermal records from holes drilled through the polar ice caps reveal broad maxima that reflect the colder temperatures during glacial times. In Greenland boreholes, this broad glacial feature is preceded by a narrower one, which requires a temperature oscillation to have occurred in the late Holocene. The timing of this swing broadly matches that of the Medieval Warm Period to Little Ice Age oscillation. Its magnitude is about 2°C (13). The borehole temperature record for Greenland thus appears to reflect the climate changes thought to have led to the establishment and eventual abandonment of the Viking colonies in southern Greenland (2). It is also consistent with records in the Swiss Alps.

Far Field Evidence

Evidence for the Medieval Warm Period from other parts of the world exists but is spotty and/or circumstantial. From an analysis of 6000 continental borehole thermal records from around the world (14), Huang et al. conclude that 500 to 1000 years ago, temperatures were warmer than today, but that about 200 years ago, they cooled to a minimum some 0.2° to 0.7°C below present. However, as is the case for the thermal profiles in ice, those for continental boreholes are highly smoothed. Although suggestive, the fluctuation postulated by Huang et al. does not prove that the Medieval Warm Period was global in extent.

Evidence that climate during the latter part of the Medieval Warm Period was much different from today's comes from moisture records for the western United States. Stine has studied lodgepole pine trees rooted at 8 to 19 m depth in Lake Tenaya in the high Sierra Nevada (15). For the trees to have grown, the lake must have been nearly dry. In contrast, only once during the past 50 years has the lake not overflowed during snowmelt. Using radiocarbon dating and ring counting, Stine has shown that for 70 years before 1093 A.D., the lake stood at least 13 m below its outflow spillway, and for 141 years before 1333 A.D., it stood at least 11 m below its spillway (16). Stine has documented similar events at Mono Lake and the Walker River (17). He concludes that late in the Medieval Warm Period, California experienced several decade-long periods of profound drought.

If, as Bond et al. (3) suggest, the cyclic changes in ice-rafted debris composition reflect oscillations in the strength of the Atlantic's conveyor

circulation, one might expect temperature changes in Antarctica to have been opposite in phase to those in the North Atlantic, as was the case during the last deglaciation (18). Clow has carried out a deconvolution of the temperature record at the Antarctic Taylor Dome site (19). His reconstruction shows that the air temperature was 3°C colder during the time of the Medieval Warm Period than during that of the Little Ice Age. This record suggests that conditions in Antarctica underwent an antiphased oscillation during the Medieval Warm Period-Little Ice Age period.

The Case for a Global Event

The case for a global Medieval Warm Period admittedly remains inconclusive. But keeping in mind that most proxies do not have adequate sensitivity, it is interesting that those capable of resolving temperature changes of less than 1°C yield results consistent with a global Medieval Warm Period. To test whether this is indeed the case, we require Holocene snowline fluctuation records for tropical and Southern Hemisphere sites and continued studies of wood and peat exposed by the continuing retreat of Northern Hemisphere glaciers. As the world's mountain glaciers continue to retreat, ever more evidence for past Holocene warm episodes will be exposed.

One might ask why the strength of the Atlantic's conveyor circulation oscillates on a time scale of one cycle per 1000 to 2000 years. I suspect that it has to do with the export through the atmosphere of water vapor from the Atlantic to the Pacific Ocean. The magnitude of this export has been estimated to be $(0.25 \pm 0.10) \times 10^6$ m³/s (20). If this freshwater loss were not balanced by the export of salt from the Atlantic, the latter's salt content would rise at the rate of about one gram per liter each 1500 years. Such an increase in salt content would densify cold surface water by an amount equivalent to a 4 to 5 K cooling, thereby strongly altering the buoyancy of surface waters in the North Atlantic and hence their ability to sink to the abyss.

I believe that this salt export is not continuous but episodic. The salt content of the Atlantic periodically builds up until a strong conveyor circulation mode is turned on, causing the salt content to drain down. Eventually, a weak circulation mode kicks in, allowing the salt content to build up again. I have suggested previously (21) that an apparent mismatch between radiocarbon and chlorofluorocarbon-based estimates of the rate of deep-water formation in the Southern Ocean may reflect a change in circulation after the Little Ice Age.

The geographic pattern of Holocene climate fluctuations remains murky, but several things are clear. The Little Ice Age and the subsequent warming were global in extent. Several Holocene fluctuations in snowline, comparable in magnitude to that of the post-Little Ice Age warming,

occurred in the Swiss Alps. Borehole records both in polar ice and in wells from all continents suggest the existence of a Medieval Warm Period. Finally, two multidecade-duration droughts plagued the western United States during the latter part of the Medieval Warm Period. I consider this evidence sufficiently convincing to merit an intensification of studies aimed at elucidating Holocene climate fluctuations, upon which the warming due to greenhouse gases is superimposed.

Mike,

you are really the most appropriate person to be the lead author on this -
I was just volunteering myself as the unfortunate soul who has to bear the
brunt of Wallys wrath

Tom

ps Peck would be fine of course but I don't know whether we want to get
him tangled up in the acrimony - we could of course ask for his comments
beforehand

>HI Tom,

>

>Thanks--I was thinking this too. Ray held out a real olive branch to Wally

<x-flowed>

Dear All,

I was away over the weekend at Bowdoin College in Maine, giving a talk about the

last 1000 years. There were three others as well on other paleo aspects,

Richard Alley,

Gary Clow and Wally Broecker ! The latter briefly mentioned to me that he had had

something in last Friday's Science, which was getting at the Mann et al.

series. He

didn't have a copy so we've not seen it here yet. I tried to get a copy

of Science on

the bookstand at Logan airport last night - I guess it's not sold that way !

Wally was going on about this 1500 yr cycle of Bond's, which seemed pretty flimsy.

I was showing all the various series in a general talk - and I used some

of the overheads

from the upcoming Science paper. This is due to appear in the issue for the last week

of April. It is all accepted now. I will forward if you'll all abide by

the Science rules. Both

Wally and Alley seem convinced that the climate of Greenland changed by 10 C in

the space of 2-3 years at times in the past (Y Dryas etc). I had long talks with both

and they don't seem to have got their heads around spatial scales (local

changes

and hemispheric). Also they don't seem to realise where we are coming from. He

has a downer on trees (believes all the multiproxy series depend exclusively on

trees) but he thinks Ed Cook is a great scientist. The latter is true, but he might

just think that because he's at Lamont. I did tell him that Keith's paper

on the age

banding is out in JGR. I should send him a reprint and maybe ask that great scientist to go and explain it to him ! Ed's in NZ at the moment. Also Wally believes much more in glacier advances/retreats. I'll get Keith to send him Sarah's paper where the long Tornetrask reconstruction is shown to agree with Storglaciaren advance/retreat dates from moraine evidence. Also Sarah's been working on similar glaciers in the Swiss Alps with long tree-ring reconstructions. One interesting thing was he didn't seem to realise that a lot of the tree-ring reconstructions use density. Seemed to think they were all ring widths and there had to be moisture changes we were not accounting for.

It is easy to respond to a Perspectives piece. Some of you did it with respect to one of mine. I'm not sure it will achieve much - it won't come out before the paper in the last week of April. I need to wait to see what he says. Our paper (me, Tim and Keith) clearly says that the MWP couldn't have been warmer (for the NH average) than the late 20th century.

Another possible reason for not doing anything is that the IPCC report will be out soon. The summary is written in pretty clear language.

The above is my first thoughts, not having read the piece and just got off the flight back.

Best to ignore Wojciek. All he seems to want to do is deflect us into responding.

Cheers
Phil

Subject: Proposed TGCIA meeting: 30th May to 1st June, Amsterdam
Date: Tue, 27 Feb 2001 08:32:21 -0500 (EST)

Dear TGCIAers:

A proposed date/place for the next TGCIA meeting is: 9.00 on Wednesday 30th May to 14.00 on Friday 1st June at Shell International Bldg, Amsterdam. Rob Swart and colleagues at WGIII TSU have kindly agreed to be local hosts. I suggest this date after consulting with 9 TGCIA members present at WGII plenary at Geneva last week. The window is narrow between IPCC and SUBSTA meetings (the latter is now almost certainly delayed until mid June). Please put this date in your diary, but also let me know of any major conflict with IPCC/UNFCCC-type schedules.

Unless I hear to the contrary(*let us say by Monday 5th March*), the proposal is that this date stands .

This meeting is particularly important because top of the agenda from our last meeting is consideration of developing a 'one-stop-shop' for data and guidance for scenario-based climate impacts assessment, which would lay the foundations for compatible research for the next IPCC assessment (whatever form it may take). We might well also consider what recommendations to make concerning the form of the next assessment (a subject probably on the agenda of the IPCC London Plenary in September).

More follows next week, assuming these dates hold, about agenda and arrangements.

Kind regards,
Martin parry

Mike et al,
Sorry about the multiple sendings. I've forgotten my glasses and couldn't see I'd missed a comma.
Another thing to point to is the special issue of Climatic Change by Astrid Ogilbie and Trausti Jonsson. They point to the LIA not being very appropriate in Iceland.

Cheers
Phil

Mike,
So Julia handled it. Even she thought it was handwaving, but it passed the usual Science review process. Obviously this isn't great as none of us got to review it. Odd that she didn't send it to one of us here as she knew we were writing the article she asked us to ! Anyway that is water under the bridge.
As for authorship we have this article coming out so this rules us out. Tom isn't keen and he's away. Wally told me he didn't reckon Tom, so Tom has got the right vibes. Julia is asking us to go ahead and hinting at a joint response.
One possibility is either you or Macolm taking the lead. Malcom and Henry wrote the MWP piece in Climate Change in 94. Keith and I think something pointed about the MWP is the way to go. Could add in that even the two warming periods in the 20th century don't show warming everywhere - especially the early 20th century.
Remember that we are all basically averaging long series together and if one site shows a big warming/cooling then the average will to a lesser extent.
Also bring in

a few of the papers where people have compared tree based reconstructions with glacial advances/retreats (eg Raper et al in J. Glaciology and Luckman et al in the Holocene. Also there are more in that Interhemispheric Linkages Book of Vera and work by Ricardo Villalba and others).

Basically need to point to a load of literature that we would expect someone writing an article of this type to be aware of. Also the North Atlantic isn't the last word in NH and global averages. Clearly said in Hughes and Diaz and papers therein.

Also the latest IPCC report will use and reference the latest curves, but from 1400 they are not that different from Bradley and Jones (1993), so why the fuss now.

Clearly the MWP is the issue that has got a few worked up, but we have concluded nothing that couldn't have been gleaned in 1994. Maybe we're stating it more clearly now, but the recent warmth of the 1990s is a factor as well.

Cheers
Phil

>
>Dear Phil
>
>Thanks for your message regarding Wally Broecker's Perspective. I am of course aware of this Perspective coming out - I did handle it - I realized that it was perhaps a bit handwaving in parts but I thought the message was interesting and the article passed the usual screening. But we are always open to criticism! So please do send a letter to us; you can send it directly to me, and you may cowrite it with Tom Crowley and Mike Mann or you can send separate letters (if the concerns overlap a lot then one letter is perhaps better than several). The letter will be handled through our letters department, and we will get a response from Wally plus possibly outside review before we make a decision to publish.

Dear Mike et al,

I offer the following comments on your letter for your consideration.

It seems to me there are 2 primary issues to address:

- (A) what does proxy evidence say about whether the Medieval Warm period was global
- (B) what do we know about potential mechanisms for the Medieval Warm period
 - (i) evidence for a forced phenomenon
 - (ii) evidence for internal variability

Issue (A) is currently dealt with in your sections (1) and (2). One point that could be perhaps conveyed more clearly is the necessity of using the spatial information conveyed in (multi) proxy reconstructions, rather than overly interpreting sets of local proxy evidence. I felt this point could have been stressed more, and is one which the casual reader may not appreciate.

Issue (B, Bi) is in your section (3). I suggest a more explicit mention of conclusions with regard to the Medieval Warm period in recent work on this topic. The first statement in this section doesn't provide (I don't think) explicit evidence to back itself up. The sentence starting "These results ..." could be more explicit about what those studies show with respect to the Medieval Warm period, in addition to the more general statement about the partitioning between forced and internal variability. A reader could ask "Ok, if 50% of the variability is explained by volcanic and solar forcing, that doesn't exclude the other 50% playing a strong role for events such as the Medieval Warming." Such a question could be dealt with in advance by stating what role these studies suggest for radiative forcing in the Medieval Warm period.

For issue (Bii), I would suggest being explicit that it is incumbent upon authors to provide some evidence to support their speculation. What evidence can the author provide to support his speculation concerning the role of the THC in the Medieval Warm period? Rather than explicitly stating this is not a likely mechanism, I would contrast the speculation he has offered on this topic to the stronger (in my opinion) evidence provided by modeling studies to

support the idea of the importance of radiative forcing.

... a few more minor comments

(1) I agree with the overall message you are conveying, but might choose somewhat differing wording in a place or two. The statement is made "(1) It cannot reasonably be argued that the Middle Ages were as warm as the 20th century at global or hemispheric scales." This might be a bit strong ... I would think one can have a reasoned discussion on this topic. Perhaps something like "We strongly disagree with the assertion that the Middle Ages were as warm as the 20th century at global or hemispheric scales."

(2) In the second to last sentence, I would add the qualifying phrase "on planetary scales" after the text "... responsible for centennial-millennial changes ...".

Regards,
Tom Delworth

ps The central issue is one that I have not been heavily involved in, and thus don't think it's appropriate for me to sign on as an author. Good luck, and please send me a copy of your final submission.

pps I previously provided to Tom correlations between the THC and global/hemispheric temperature based on a 900 year run of our R30 coupled model. These correlations were relatively low (0.27), but probably significant. The applicability of those correlations to the issue of the Medieval Warming may not be strong. If the Medieval Warming is a multi-century event, then I should really be looking at the correlations of low frequency (>50 years) filtered model output from a run of several millenia duration. Thus, the 900 year run may not be applicable. I will revisit this topic using a multi-millennial R15 coupled run, but probably won't have any results today. I don't think that would change the essential conclusions, however. I recall that experiments with the R15 model in which the THC was substantially weakened through the addition of fresh water to the North Atlantic provided strong regional temperature anomalies, but their global expression was small. These experiments are being repeated with the higher resolution model.

In light of these issues, I suggest that the focus be not so much on saying the THC cannot be responsible for the Medieval Warming, but rather on saying (1) there is strong evidence for a substantial role of radiative forcing, and (2) the burden is on the author to provide evidence for the role of the THC.

?

Thanks for clarifying Tom,

Yes, these are my sentiments as well, and I would conditionally sign-on to this effort. In the meantime, I think there is a lot of good science to be done!

Subject: Some thoughts on climate change proxy temperatures in the last 1,000 yrs
Date: Fri, 2 Mar 2001 15:54:57 -0800

<x-rich>Folks,

Two points here:

1. I read with some consternation Wally Broecker's latest piece in Science (23Feb. 2001). First you can all take up some other topic since Wally says only Boreholes and treeline changes are accurate enough to do low frequency trends. What does he mean by "only two proxies can yield temperatures that are accurate to 0.5°C"? and do you agree that tree rings and sediments, etc are not sufficiently accurate to exhibit correct low frequency trends?

2. Here are some references to recent Holocene time-frame records you probably have seen, but just in case... I found them interesting without knowing how good or representative they are.

Surprisingly they were given me by one who cited them as examples of evidence for a MWP and LIA. I read them differently but they caused me to consider one question I hadn't heard discussed (see below).

Based just on these four, one comes to the following tentative conclusions and observations:

Conclusions:

*MWP was a generally warm time interspersed with coolings and not well synchronized hemispherically or globally.

*LIA was global and capable of better (but not completely) synchronized large amplitude variations

*20th Cent. was the only time when all records agree (tree ring problems with CO2?)

MIGHT THIS RELATIVE UNIFORMITY BE USED AS A CHARACTERISTIC OF 20TH CENTU WARMING THAT SETS IT APART FROM PREVIOUS CLIMATE CHANGES?

*Borehole inversion is too smoothed to be of much use but it does indicate a larger temp amplitude if it weren't smoothed. ~1.5°C

And this brings up my question. How one averages these records.

One way would be to note that the temperature amplitude (1000 - 1950) for each is ~1.5°C. Thus you could conclude that hemispheric/global climate varied by over a degree Celcius (although with regional differences)

Another way would be to average the records. The resulting temperature amplitude would be smaller because extremes would cancel since variability is large and each region's extremes occur at different times.

Thus, if people simply looked at several records they would get the impression that temperature variations were large, ~1.5°C. Imagine their surprise when they see that the ensemble averages you publish have much smaller amplitude.

Comparison of amplitudes is given below (although difficult to do since amplitude depends on averaging so these are very approximate).

Approximate Temperature Amplitudes for period 1000-1950

Mann et al 1999	~0.5
Jones et al 1998	~0.8
Crowley and Lowery	???
Briffa 2000	???
Dahl, Jensen	~1.5
Huang, et al	~0.8 (500 yrs only)
Overpeck et al	~1.3 (400 yrs, polar only)
Bradley & Jones (93)	~0.7 (600 yrs only)

(Not surprising that the contrarians take great exception to Michael's small amplitude.)

This is important in the current debate even, it would appear, with people like Wally. I have been looking for what the real issue is between researchers like yourselves and skeptical scientists. Politics and agendas aside, I think it is close to this.

Anyone looking at the records gets the impression that the temperature amplitude for many individual records/sites over the past 1000 years or so is often larger than 1°C. They thus recognize that natural variability is unlikely to generate such large changes unless the sun is having more effect than direct forcing, or there is some fortuitous but detectable combination of forcings. And they see this as evidence that the 0.8°C or so temperature rise in the 20th century is not all that special.

The community, however, in making ensemble averages gets a much smaller amplitude ~0.5°C. which they say shows that reasonable combinations of solar direct plus volcanos and internal variability with the help of THC can indeed explain this AND the 20th century warming is unique.

Thus, the impass--one side pointing to large temperature variations in many records around the globe and the other saying "yes, but not synchronous and so averaged hemispherically no big deal.

But, just replying that lack of synchronous events (sometimes by a few decades) is the reason might not be enough. It seems to me that we must go one step further. We must address the question: what forcings can generate large amplitude temperature variations over hundreds of years, regional though they may be (and, could these occur at different times in different regions due to shifting heat inertia patterns)? If we can't do this, then there might be something wrong with our rationale that the average is low amplitude even though many regions see high amplitude. This may be the nubbin of the disagreement, and until we answer it, many careful scientists will decide the issue is still unsettled and that indeed climate in the past may well have varied as much or more than in the last hundred years.

(Also, I note that most proxy temperature records claim timing errors of +-50 years or so. What is the possibility that records are cancelling each other out on variations in the hundred year frame due simply to timing errors? as in hitting or missing C&L's triple warming peak 1000-1200 AD)

Regards,

Referendes to proxy temp records

<excerpt>(1) Bodri, L. and V.Cermak Climate change of the last millennium inferred from borehole temperatures: Regional patterns of climatic changes in the Czech Republic - Part III, Global and Planetary Change, 21, 225-235. 1999

As with other borehole data the record is incredibly smoothed. It has essentially three warming features.

from 1000 to after 1500 there is a broad warming pulse;

1550-1750 cooling

1750-1850 warming

1850-1900 cooling

1900-1950? rapid warming <underline>Total amplitude ~1°C (1.5°C if not smoothed?)

</underline>

I don't know what to make of the more than 500 year warming pulse. Most records show warming either in the 1100's or 1200's but usually not both.

The rest of the record looks reasonable given the smoothing.

Hi Tim,

That all sounds great, and indeed, the 19th century will be a *hot* topic (pun intended) as we try to rectify Tom's model response w/ the instrumental record and proxy reconstructions. Ironically, the 19th century is one in most dispute over the past millennium, it seems!

You accurately summarize what my understanding is of the breakdown of lead roles. I don't see any reason for changing that. I think Scott and I will have our hands full w/ the other items, so if you can take the lead role on the MXD paper (comparing the two methods, etc.) that would be great.

My intention is to give you and Scott full credit for anything I show at meetings that is a result of mutual collaboration. Of course, both of you are co-authors of my EGS talk.

So all sounds great! Scott: when Tim sends revised plots, can you prepare some revised ppt files and let me know when they are available to download? Hope to get all this straightened away next week after I return from the frozen north (Michigan)...

mike

Subject: Re: verification results
Date: Thu Mar 15 16:38:31 2001

Mike & Scott,

I've redone the verification against instrumental temperatures for 1856-1899. Previously I'd used 1856-1900, but I've now realised that 1900 is not part of the verification period (the pattern correlation = 1 gave it away!). So I've now stopped in 1899. It makes virtually no difference to the quasi-hemispheric series and their correlations. What it does affect is the grid-box by grid-box temporal correlations, since I was previously using one perfect value at the end of each series. So the correlations are mostly a bit lower now, though still fairly good I think. There's a reasonable area with $r > 0.3$. Signal to noise should increase fairly dramatically if some kind of regional averaging were done. I've outlined the boxes that actually have chronologies in them. There's not enough instrumental data to verify the more northern ones, but the European and USA ones do well (r in range 0.5 to 0.9). The more distant oceanic regions are a bit poorer, except the northern Indian Ocean. So that's it for the verification, for the moment.

I've compared the 1404-1855 (i.e., pre-instrumental) reconstruction with the Briffa et al. and Osborn et al. reconstructions. Correlations are all quite high (0.7 to 0.85) for the quasi-hemispheric series, while the pattern correlations average around 0.6. The box-by-box temporal correlations show many boxes with r in the range 0.6 to 1.0, indicating little sensitivity to the method used. One notable feature of the latter results is that there's less agreement in the boxes that actually have trees than those don't! There's two different interpretations of this that I'm working on, which seem equally possible. More later. I was going to send the time series and maps from this comparison, but I've just realised that I'm using anomalies from two different baselines (1961-90 for ours, 1901-60 for REG-EM) so the % variance explained and the time series aren't right - that'll have to wait till Friday now.

Tim

Dear everybody,

I am still busy compiling the report from the kickoff meeting (and I
also still await some input pieces from some of you...).

For those of you who could not be there, let me just say that I
enjoyed very much to see the group here, and to witness the really
lively and productive discussions. Let's keep it that way.

While U wait for the report - I would like to get you thinking about
the project again by circulating the second draft of a small piece
which is edging towards a working definition of vulnerability, mostly
written by Richard and with input from Pete, Miguel and myself. All
comments are welcome. This is not intended for publication of course,
but it could be a start of something more substantial in due course.

So please send me the elements still missing for the overall report,
and comment to the four authors about the vulnerability piece.

Best regards,

Wolfgang

Internal ATEAM document ôTowards a definition of
vulnerabilityàö û do not cite
Draft version 2.0 (16/3/01)

TOWARDS A DEFINITION OF VULNERABILITY
OF ECOSYSTEM FUNCTIONING TO GLOBAL CHANGE

Richard J.T. Klein, Pete Smith, Miguel B. Ara·jo and Wolfgang
Cramer

This document aims to stimulate the discussion of
vulnerability to global change, which is a key feature of the
EU project Advanced Terrestrial Ecosystem Analysis and
Modelling (ATEAM). The goal of ATEAM is to develop an
operational quantitative assessment of vulnerability across
European ecosystems. The rationale for this assessment and its
initial elements are also found in this document.

Common features in present definitions of vulnerability

Vulnerability is a multi-dimensional concept that has been a
topic of study in many different scientific disciplines,
ranging from anthropology and psychology to economics and
ecology. As such, it has been defined and assessed in many
different ways for many different purposes. The scientific
literature provides many examples of vulnerability
assessments, each with their own explicit or (more often)
implicit interpretations of what vulnerability means to the
object of study.

In spite of this diversity the various interpretations of vulnerability have a number of things in common:

1. Vulnerability is always an attribute of a system, in the broadest meaning of the term. Systems that may be vulnerable include individual people, communities, countries, economic sectors, landscapes, resources, ecosystems and so on. Importantly, in ATEAM the system of interest is not ecosystems per se but the set of functions that ecosystems perform in providing goods and services to human society.
2. Vulnerability always refers to some potential of or exposure to harm or damage. It is therefore meaningful to specify exactly to which forcing a system is thought to be vulnerable. In ATEAM multiple forcings are considered, all related in some way to global change. In response to needs expressed by the European Commission these forcings are the increasing atmospheric concentration of CO₂, the climate change that is the result of this increasing concentration, as well as the effects of changing land use and land-use policies.
3. Definitions of vulnerability tend to capture some notion of the extent to which the system would be unable to avoid, defend itself against, cope with, adjust to or otherwise prevent or minimise potential harm or damage. This mechanism of damage prevention or minimisation (termed adaptation in the context of climate change) is important because it defines the difference between the potential harm or damage and the actual or residual impacts that will occur. It can be argued that if a stress-exposed system has the ability to avert the potentially severe impacts that could ensue from this stress, then it is not vulnerable (footnote 1).

The first assessments of vulnerability to climate change (such as the First and Second Assessment Reports of the IPCC and many national vulnerability studies) were carried out without considering adaptation as an important aspect of vulnerability. These assessments implicitly assumed present-day behaviour and activities to continue unchanged in the future, irrespective of how they would be affected by climate change. By ignoring adaptation these studies did not distinguish between potential and residual impacts and thus their results represented serious overestimates of the system's vulnerability. On the other hand, the studies served to generate awareness of the potential magnitude of impacts and of the need for adaptation.

A recent discussion of vulnerability: the IPCC Working Group II

Each of the aforementioned features of vulnerability was incorporated in the proposed definition of vulnerability in

the IPCC Working Group II Third Assessment Report, which was as follows:

The degree to which a system is sensitive to and unable to cope with adverse impacts of climatic stimuli. Vulnerability is a function of a system's exposure and its adaptive capacity.

However, the IPCC Working Group II Plenary meeting in Geneva (13-16 February 2001) adopted a somewhat modified and expanded definition in the final, government-approved version of the Summary for Policymakers. The adopted definition no longer captures the important notion that vulnerability depends on both potential impacts and the inability to cope with these impacts, as was indicated by the word "and" in the first sentence of the above definition:

The degree to which a system is susceptible to, or unable to cope with, adverse effects of climatic change, including climate variability and extremes. Vulnerability is a function of the character, magnitude and rate of climate variation to which a system is exposed, its sensitivity, and its adaptive capacity.

Building blocks for a definition to be used in ATEAM

The former definition of vulnerability captures the various aspects of vulnerability discussed above but it is likely to be too broad to be made operational in ATEAM. ATEAM addresses the interaction between ecosystems and society and in particular the provision of goods and services by ecosystems for human use. Of relevance to ATEAM are therefore not only the exposure and adaptive capacity of ecosystems to climate change but also the adaptive capacity of human systems in relation to a change in the provision of ecosystem goods and services. To develop a meaningful definition of vulnerability for ATEAM it could be useful to explore a number of related concepts: risk, sustainability and resilience.

A relatively widely accepted interpretation of risk is that it is a function of the probability of occurrence of an event combined with an estimate of the magnitude of its impact. For example, in the context of species conservation risk can be seen as a measure of the probability that a negative event (i.e., a threat) combined with the individual species's response to these events (i.e., an indicator of species's vulnerability) would lead a species to extinction (Araujo and Williams, 2000).

Amongst the many definitions of sustainability, a useful one is based on the conservation and substitutability of different types of capital: human-made capital, natural capital, human capital and social capital (Serageldin and Steer, 1994). Sustainable development, of which the most widely used

definition is "development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (WCED, 1987), prescribes that the total stock of capital does not decrease over time. Whether or not substitution and compensation of different types of capital are allowed depends on the preferred level of sustainability (cf. weak versus strong sustainability).

The relationship between sustainability and ecosystem vulnerability is based on the extent to which external forcings lead to a decrease in natural capital and thus in the potential of ecosystems to provide goods and services for human use. A possible (anthropocentric) definition of sustainability in the context of ATEAM could therefore be:

The ability of an ecosystem to provide humans with goods and services in the present, without compromising the ability of future human generations to obtain these ecosystem goods and services in the future.

The concept of resilience is well known in ecology, although two distinct interpretations of the term exist. As defined by Holling (1973), resilience determines the persistence of relationships within a system and is a measure of the ability of these systems to absorb changes and still persist. According to Pimm (1984), however, resilience describes the speed with which a system returns to its original state following a perturbation. Holling (1973), on the other hand, considered this to be the stability of a system, whilst Pimm (1984) referred to stability as the combination of resilience, resistance, persistence and variability.

In an attempt to define the resilience of the Dutch coast, Klein et al. (1998) distinguished between a morphological, an ecological and a socio-economic component of coastal resilience, each of which represents another aspect of the coastal system's capacity to cope with perturbations. They described coastal resilience as a measure of the extent to which a coast is able to respond to external pressures without losing actual or potential functions:

The resilience of the coast is its self-organising capacity to preserve actual and potential functions of coastal systems under the influence of changing hydraulic and morphological conditions. This capacity is based on the (potential) dynamics of morphological, ecological and socio-economic processes in relation to the demands that are made by the functions to be preserved.

Given the focus of ATEAM on ecosystem services, we might want to work towards a similar type of definition of vulnerability, whereby vulnerability could be described in terms of the likelihood that an ecosystem loses a significant amount of its capacity to provide goods and services that are important to

society. A definition that includes the temporal dimension of global change and sustainability could describe vulnerability in terms of the risk of ecosystem sustainability being compromised. Before suggesting a "final" definition, however, we would like to invite views and suggestions from the entire ATEAM consortium.

<x-flowed>

Phil et al,

There is a problem w/ figure 4 (and discussion thereof) in your paper to appear in Science. Unfortunately, I didn't catch this until I re-read the paper just now. You haven't shown the right Mann et al NINO3 reconstruction. Are you sure you have used the *cold-season* NINO3 reconstruction, as discussed (and available) in the Mann et al Earth Interactions paper, and not the annual mean reconstruction!!

http://www.ngdc.noaa.gov/paleo/ei/ei_reconsb.html

I don't believe that has the trend that the series you show does. That NINO3 series agrees closely ($r=0.63$) w/ the Stahle et al series (once the sign has been flipped on that series, and the off-by-one-year date convention is taken into account), far closer than what you have shown. I'm pretty sure you've used the wrong series.

Moreover, it is inappropriate to refer (as you do) the Nino3 reconstruction as an SOI reconstruction, no matter whether it has been renormalized, sign-switched, etc. There are fundamennal differences between the low-frequency behavior of NINO3 and SOI, (consider for example the 20th century!) and they aren't dynamically equivalent! To say there is a "long-term trend" in our "SOI reconstruction" is extremely misleading. There is a long-term trend in our *NINO3* reconstruciton. Only Stahle produced an SOI reconstruction, and it is only meaningful to correlate the two at annual timescales where they should similarly reflect largely interannual ENSO variability.

Moreover, I don't think this is true (or as true) of our colld-season NINO3 series, which is the right one to use. Hopefully, you still have a chance to change this in the galleys, etc.

Thanks in advance for your attention to this,

mike

Subject: Fwd: RE: kyoto survey - press inquiry from the THES
Date: Thu Apr 5 11:59:31 2001

Simon,

Could you - or Vanessa - buy a THES today from the paper shop and check this out. I would quite like to draft a short letter to THES as suggested by Steve. But I need to see how the issue was presented in this week's issue.

Thanks,
Mike

X-Mailer: Internet Mail Service (5.5.2653.19)

Dear Mike,

thanks for that. I feel terrible but despite the pain it cost to reply to the survey, the deadline has now passed. We had such a high response rate that we decided to run the piece in this week's paper while the issue of the US withdrawl from the protocol was still high in everyone's mind. So I cannot include your responses. However, you make a number of very significant points, not least your reply to question 2 on the strength of the evidence and the political framework outlined in your final sentences. I wonder - and I know this is pushing it - whether you might consider rearranging some of these sentences to form a brief letter to the editor for the following week's paper? I would like this issue to stay alive in the THES and allow the paper to play a small role in persuading as many scientists as possible to take part in a scientific/political debate that may contribute to influencing those people who *can* change things. Not an original objective, I know, but the THES does have a fairly unique position within the academic community and hence a responsibility. Anyhow, sorry for the bad news

best wishes

Steve

Subject: Re: kyoto survey - press inquiry from the THES

Steve,

I hate these sort of questionnaires since Y or N answers are barely adequate. However, I've given it a go with some other comments (by the way, Prof. Trevor Davies is Head of my School here at UEA - I am only Director of a Centre within the School, albeit a highly relevant one!). You can quote me if appropriate, but let me know before hand.

Mike

At 12:30 02/04/01 +0100, you wrote:

>

>all the bets

>

>Steve

>

>1: Do you believe human activities are at least in part responsible for
>driving global climate change?

YES

>2: Do you feel the evidence for this is sufficiently strong to start
>reducing emissions?

NO - to reduce emissions requires more evidence than that humans are altering climate. We need to know something about the potential risks associated with future climate change, whether these risks can be minimised through adaptive action and then have some socially negotiated basis for deciding about the necessity and extent of desirable emissions reductions. On none of these issues do we have a good basis to work from. The precautionary principle, if chosen, would imply start reducing emissions now - but I am not convinced a blind application of the precautionary principle in this case is the most appropriate instrument.

>3: Do you think the measures proposed at Kyoto were too weak, correct, or
>too strong?

The 5.2% emissions reduction by 2010 by Annex I countries were not driven by science but by real-politik. By definition they were the best achievable. The real issue however is not about target setting - it's about the dynamics of change worldwide in energy technologies, investment strategies, consumer and community behaviour and aspirations, etc. It is *these* things that in the end will deliver a safer climate - not the Protocol per se. More attention should be directed at the diverse and myriad set of actions needed to decarbonise our societies.

>4: Are you disappointed that George Bush has abandoned the Kyoto agreement?
YES - but it is too early to say that Kyoto is dead. The USA does not have the power of veto - and Bush will have to propose some climate management strategy of his own. We wait and see.

>5: Should the rest of the world press on with the agreement without the
>United States?

Probably YES. This can be achieved and should provide valuable lessons in global climate management which we can learn from in the long-term.

>6: Do you feel the US should be allowed to count carbon sequestration
>measures such as planting new forests towards any carbon emissions
>reduction target?

YES. The UK are doing it in their national climate change programme so why not the USA?

>7: Are you optimistic that there will be a new emissions control agreement
>within the next 12 months?

A 'new' one? We haven't got one yet. I would think maybe not in the next 12 months, but the critical issues about global climate management will be clearer.

>8: Should the Kyoto preliminary targets be watered down to gain the
>Americans' support?

NO. If the USA don't like them, let them not ratify or propose a strategy of their own.

>If you would like to add any comments to this survey as to the
>implications of the US's rejection of Kyoto for the planet, what UK can do
>about it or what role scientists can play in this debacle, please do so.

In a literal sense the implications for global climate are trivial - what will affect the course of global climate (and only then climate beyond about 2030 - up until then climate is pretty much pre-determined by inertia in the system) in the long-run are the effects of cumulative decisions taken by many, many people/governments/businesses over the next 10-20 years. Let's not kid ourselves that the USA President is more powerful than he would like to think. The planetary system is much bigger than one 4-year term of a US president.

The UK is playing a key role both within the negotiating machinery of the FCCC, in pioneering new scientific analyses, and in working out new forms of adapting to climate change. This momentum in the UK is not going to be

halted by Bush.

Scientists need to be there to point out the long-term nature of the problem - it is not a classic political issue where a one-term government can solve or worsen the problem. Scientists need to point out that for long-term planetary management we need new analytical tools, new criteria for investment decisions, a new appreciation of the concept of global citizenship. What climate change forces us to do is to think about the influence we are having on the quality of life for the next generation but one - not our own generation or even our children's generation. Conventional politics is not a system geared up for this challenge.

<x-flowed>

Hi Tim,

THanks for looking into this so quickly. I agree w/ your assessment. It is probably just the fact that the signal of interest in SOI and NINO3 is really the interannual signal, and this is not evident in the low-frequency component shown, which emphasizes discrepancies that are actually small compared to amplitude of the interannual signal present in both Stahle et al and Mann et al. So I would urge showing the annual reconstructions in this case, rather than smoothed for this reason...

In IPCC we only chose to show 1700 to present, which is a better calibrated/verified interval than back to 1650, so I'd encourage you guys to restrict it to 1700-present if you can. Other than that, I think it is important to acknowledge that SOI and NINO3 have different low-frequency trends over the 20th century, and might well have different trends in the past. It is true that many of the proxies used are sensitive to the SOI (e.g. mexican tree rings), but others are sensitive to Pacific SST (e.g. corals from GBR, New Caledonia, Galapagos) and our claim is that the calibration process will select out the best estimate of the temperature patterns, rather than SLP patterns, associated w/ ENSO, from the multiproxy network. In the future, we'll be going after SLP reconstruction too, and it'll be interesting to see what the difference is.

I hope that clarifies. Please let me know if I can be of any further help, provide further clarification, etc. Thanks again,

mike

Chick,

look at the instrumental record! there are huge differences between different regions - Alaska has warmed substantially while eastern North America cooled after the 1950s. locking onto local records, no matter how beautiful, can lead to serious errors. If the ice cores are so infallible why do they give substantially different stories for grip and gisp2 over the last 1500 years?

the bottom line is that one cannot make a robust case that decadal hemispheric temperatures over the last 1500 years were even as warm as the late 20th century, much less warmer.

Tom

Hi Mike,

No problem. I am quite happy to work this stuff through in a careful way and am happy to discuss it all with you. I certainly don't want the work to be viewed as an attack on previous work such as yours. Unfortunately, this global change stuff is so politicized by both sides of the issue that it is difficult to do the science in a dispassionate environment. I ran into the same problem in the acid rain/forest decline debate that raged in the 1980s. At one point, I was simultaneously accused of being a raving tree hugger and in the pocket of the coal industry. I have always said that I don't care what answer is found as long as it is the truth or at least bloody close to it.

Cheers,

Ed

<x-flowed>

Hi Ed,

On the road, but just had to chime into this debate briefly.

What you say is of course true, but we have to start somewhere. Step #1 is producing a reconstruction. Without some reasonable estimate of uncertainty, a reconstruction isn't very useful in my opinion. Step #2 is producing some reasonable estimate of uncertainty. In my mind, this is based on looking at the calibration residuals, seeing if they pass some basic tests for whiteness, normality, etc., looking at the verification statistics, and seeing if this continues to hold up in an independent sample. It is important to use the longest instrumental records we have for independent verification where possible. Of course, there may be additional biases in the predictors that are difficult to identify even in a relatively long verification interval (e.g., ultra low-frequency problems w/ fidelity). Step #3 is trying to evaluate this as best we can (looking at the frequency domain structure of the predictors themselves, seeing if there is loss of variance at very long timescales, looking at the robustness of long-term trends to standardization issues, etc.), etc...I see this as a successive series of diagnostics and self-consistency checks that iterate towards getting a reasonable handle on the uncertainties. This is the approach that we have taken, and I think it is the most appropriate...

I firmly believe that a reconstruction w/ out some reasonable estimate of uncertainty is almost useless! If the community wants to use paleodata for signal detection, model validation, etc. I believe that this is absolutely essential to do, whether or not we can do a perfect job.

I would be very surprised if Hans would disagree w/ my statement above!

anyways, my two cents on the matter...

John:

For future reference, I think its also important to clarify for you what the Dahl-Jensen, Clow et al borehole results actually show (see Dahl-Jensen et al, "Past Temperatures Directly from the Greenland Ice Sheet", Science, 282, October 1998).

In fact, the results show that the amplitude of variability over the past 1000+ years differs by a factor of 2 between the GRIP and Dye 3 borehole estimates (the latter only 865 km to the south). This is an example of extreme regional-scale variability, which should give pause to those who want to draw large-scale inferences.

However, even more importantly, they show in the case of Dye 3, the mid 20th century warm period in the record actually exceeds the Medieval warm peak! (see Fig 4, lower panel, blue curve). So here we have two temperature histories less than 1000 km apart in Greenland, which give different stories regarding the level of Medieval warmth, with at least one of the histories conforming precisely to the hemispheric trends presented in IPCC chapter 2 (note that in the chapter, we actually discuss the evidence of conflicting temperature trends in Greenland, though not specifically referring to Dahl-Jensen et al).

So do I understand correctly that you are referring to the results of Dahl-Jensen et al as conflicting with what we say in the chapter? At the face of it, this argument has no merit whatsoever. I think we should all use a better explanation from you, since you seem to be arguing publically that the Dahl-Jensen et al record undermines what we've said in the chapter.

Thanks in advance,

mike

p.s. I've cc'd in Eric Steig, a collaborator of Clow's and a Greenland & Antarctic Ice Core expert, to make sure my facts above have been presented accurately. Perhaps Eric would be kind enough to forward my email to Gary

Clow, and Gary can let us know directly if he disagrees with any of my remarks above.

Mike:

You are right: this is a disinformation campaign.
Some remarks

1) On the Christy et al grl paper, I sent the following to John following the IPCC Shanghai mtg.:

Date: Mon, 22 Jan 2001 15:39:20 -0700 (MST)
From: Kevin Trenberth <trenbert@cgd.ucar.edu>
To: John Christy <christy@atmos.uah.edu>
Subject: your grl paper

John:

Just back from IPCC. One surprise was the strong Saudi delegation distributed your recent grl paper and wanted it inserted into the SPM! In spite of the fact that you are a lead author on Chapter 2, the paper is referenced, etc. In fact Simon Brown was there.

Chris Folland made a comment about his hypothesis for this: related to changes/growth in ships. My hypothesis focusses on the buoy data. See our recent paper submitted to jgr:

<http://www.cgd.ucar.edu/cas/papers/jgr2001b/jgr2.html> also

http://www.cgd.ucar.edu/cas/papers/jgr2001a/jgr_interann.html

This shows that during and following El Nino there is an anomalous flux of heat out of ocean into atmosphere in the east Pacific of order 50 W m⁻² over many months: so ocean T warms relative to air. During La Lina flux goes other way. i.e. air warms relative to ocean.

So your results must be affected by 1997-98 event at end of series and that may explain trend differential.

Hope this helps
Regards
Kevin

i.e. the result is not as advertized.

=====

2) wrt Lindzen's paper

Here is the text from my recent Senate testimony

The determination of the climatic response to the changes in heating and cooling is complicated by feedbacks. Some of these can amplify the original warming (positive feedback) while others serve to reduce it (negative feedback). If, for instance, the amount of carbon dioxide in the atmosphere were suddenly doubled, but with other things remaining the same, the outgoing long-wave radiation would be reduced and instead trapped in the atmosphere. To restore the radiative balance, the atmosphere must warm up and, in the absence of other changes, the warming at the surface and throughout the troposphere would be about 1.2\deg C. In reality, many other factors will change, and various feedbacks come into play, so that the best IPCC estimate of the average global warming for doubled carbon dioxide is 2.5\deg C. In other words, the net effect of the feedbacks is positive and roughly doubles

the response otherwise expected. The main positive feedback comes from increases in water vapor with warming.

In 2001, the IPCC gave special attention to this topic. The many issues with water vapor and clouds were addressed at some length in Chapter 7 (of which I was a lead author, along with Professor Richard Lindzen (M.I.T.), and others). Recent possibilities that might nullify global warming (Lindzen 2001) were considered but not accepted because they run counter to the prevailing evidence, and the IPCC (Stocker et al., 2001) concluded that "the balance of evidence favours a positive clear sky water vapour feedback of the magnitude comparable to that found in the simulations."

===

Here is a more complete rebuttal, written March 23 to MacCracken.

Subject: Re: Recent Lindzen paper

Kevin Trenberth

1) The paper is based on very simple conceptual ideas that do not mesh with reality. Fig. 2 is simply not correct. For a more correct view of the overturning see:

Trenberth, K. E., D. P. Stepaniak and J. M. Caron, 2000: The global monsoon as seen through the divergent atmospheric circulation. {J. Climate}, 13, 3969--3993.

This paper also shows that the flow in the tropics is dominated by transients (and thus mixing) of all kinds. The mean overturning is only about a third of the daily mean variance for a month and much less if the intra diurnal variations and interannual variations are included.

2) The "observations" analysis makes absolutely no sense to me at all. There is a totally inadequate description of what is done and no way to decipher what a dot in Fig 5 or Fig 6 is. Given 20 months, and daily values (how was that done?) why are there only about 330 points? Why isn't Fig 6 part of Fig. 5?

In any event the results are totally at odds with other evidence. Here I refer to the Goes Precipitation Index which uses 3 hourly data on OLR, and thus on high cloud, as an index of rainfall, and it is clear from many studies that OLR generally decreases (convection and high cloud increase) with SST, the reverse of the relationship in Fig. 5.

Moreover the whole conceptual basis for anything here is surely flawed. As stated, on short time scales SST is not changing. But clouds are NOT caused by local SST, rather they arise from either transients, like the MJO, or for the ITCZ and SPCZ (which are major operators in this region), they come from moisture convergence ($P \gg E$) and so it is the patterns of SST (gradients) as well as where the warmest water is that determines where the convergence and clouds occur. Now in the warm pool, the convergence is focussed more on the edges, as that is where the pressure gradients are greater, and so the convergence is not where SST is necessarily highest.

In any case, moisture is not equal to cloudy air. Many analyses show that moisture is much more extensive, see for example Trenberth, K. E., and C. J. Guillemot, 1998: Evaluation of the atmospheric moisture and hydrological cycle in the NCEP/NCAR reanalyses. {Climate Dyn.}, {14}, 213--231.

Even with such results, other factors need to be considered.

One process might be

High SST => convergence => rainfall and cloud

OR

Less cloud => more solar radiation => higher SST

Those give opposite relations and both operate. The latter is more important in the Indian Ocean where subsidence (from the Pacific) dominates. However, it also operates over the oceans in the region in question in northern summer, because that is the monsoon season, and the main convection is over land, meaning subsidence over the ocean.

None of this is sorted out in any way in this paper.
In fact it is so bad in this regard I do not know how it got published.

In Fig 5 etc, no correlations are given, nor are their significance levels. My rough estimate is that the correlation is about 0.2 to 0.3 and that is significant if the 330 or so points are independent. But why should I have to guess at that.
Again I would question the editorial and review process.

3) Finally, I refer you to chapter 7 of IPCC which is a more balanced assessment. Lindzen was a coauthor of that with me and others. Lindzen wrote 7.2.1 and the same figure 1 in the BAMS article was included as 7.1 in chapter 7 along with similar ones from models, showing that these things are fully simulated in good models, although better with higher resolution. Anyway, his arguments were fully considered in chapter 7 and you can read it to see the result. The whole of 7.2.1, including 7.2.1.1, 7.2.1.2 and 7.2.1.3 was put together originally by Lindzen, Pierrehumbert and Le Treut, but basically the final version was rewritten by me to provide better balance. Pierrehumbert is an agnostic of sorts: disbelieves everything including models but seems to have faith in simple theories. Le Treut was sound on the modeling. I did not change the substance of what they prepared, I did reshape it and polish and it ended up in a form they accepted.

Note at the end it clearly states:
"the balance of evidence favours a positive clear sky water vapour feedback of the magnitude comparable to that found in the simulations."

The 4 subsections together are quite long and thoroughly air the issue, much more so than any previous IPCC report. For those of you who do not have it: 7.2.1 "Physics of the water vapour and cloud feedbacks" (draft written by Lindzen) is 1.3 pages, 7.2.1.1 (I think Pierrehumbert) "Water vapour feedback", is 1 page, 7.2.1.2 "Representation of water vapour in models" is 1.5 pages (Le Treut) and 7.2.1.3 "Summary on water vapour feedbacks" is half a page or so.

it is just pressure of work. I am afraid the final report did not go to INTAS . I will do it this week! I still expect we will get the money outstanding - just late . Sorry.

Keith

At 02:22 PM 5/31/01 +0600, you wrote:

Dear Keith,

Thank you for the print of collaborative article published in the J. of Geophysical Research I have received some days ago. The article is very interesting and, I think, these reconstructions will be used by many researchers of different disciplines.

At the end of the last year Janet asked me to send the account of the bank to transfer the rest money of the INTAS project (737 Euros). I have sent you the necessary form to transfer the money for my name, but the Ekaterinburg Branch of Bank for Foreign Trade did not receive the money until now. Do you know the reason?

This summer I am very busy. Along with Fritz Schweingruber and his team (four persons) we will visit many sites (using helicopter) on the North of European and Siberian Arctic and Subarctic (from the Lower of Pechora river in the west to the Lower of Khatanga river in the East). We will try to find a new sources of subfossil wood material between the Yamal Peninsula and Taimyr Peninsula, on the one hand, and between the Yamal Peninsula and Kola Peninsula, on the other hand. The second aim is to collect samples from living trees of different ages for estimating biomass changes.

After this trip I and my post-graduate student will be working in the Polar Urals (large-scale mapping of forest-tundra ecosystems over the forest-tundra ecotone for three time intervals: the beginning of the XXth century, the 1960ties and the 2000ties.

At the end of September I intend to be in Davos.

Best Regards,

Stepan

<x-flowed>

Dear All,

I'd just like to echo all the points made by Mike and Kevin. The logic behind saying that there isn't enough paleo data before 1600 yet there may have been even early millennia which experienced warming of almost 2 C per millennium escapes me. As Kevin points out they have mixed up all the various factors that force climate on interannual to intermillennial timescales. One of the main points of IPCC is to synthesize the science, with particular reference to potential future changes. Changes in the distant past (glacial and deglaciation) are of less relevance to the 21st century because of differences in boundary conditions. The last few hundred to a thousand years are clearly more important to the near future. At least from my quick reading there seems no explicit reference to changes in the thermohaline circulation.

Perhaps the paleo people on this list need to redouble their efforts to emphasize the importance of the last few thousand years, stressing absolute dating, calibration and verification. Another issue that is mixed up in the report (apart from the forcing) is spatial scales. I will try and address these at the Chicago meeting. What are the 4 useful sites ?

I just hope in the US that people read the full IPCC reports and the summaries, rather than this hastily cobbled together document. I also hope that Europeans don't read it. It has already got some air time here and may get some more with Bush here this week. Issues like star wars and capital punishment were commented upon whilst I came to work. Kyoto wasn't mentioned.

Cheers
Phil

Hi Nanne,

Thanks for your comments. I've asked Julie Cole, who is attempting a revised draft, to incorporate your suggestions. Hans or you should also provide a revised paragraph 7 that is more to your liking than what I wrote.

I'm requesting that Julie wait until the end of this week (Friday, Jun 22) to give the others time to get their comments in also. Then, after Julie provides me w/ her revised draft, I'll try to make a few more small changes and sent that onto the group for suggested final changes.

I hope this sounds acceptable to all concerned?

thanks,

mike

Subject: ECF: Agenda of the telephone conference 2 July 2001

Date: Thu, 28 Jun 2001 18:56:00 +0200

Dear member of the ECF steering committee,

The next telephone conference takes place on Monday, 2 July 2001 at 17.00-18.00 CET. The agenda is as follows (it may be modified at the beginning of the meeting):

1. Minutes of previous telephone conference (Draft sent by email on 14.6.2001) (5 Min.)
2. ECF preparatory meeting in Brussels (15 Min.)
(Agenda, Inputs: project descriptions, Outputs: workplan, sketch of a position paper)
3. ECF as an Association and/or Foundation (15 Min.)
4. Three priority projects (15 Min.)
5. Varia (10 Min.)

Important!! Please check that the telephone number where you want to be called is correct.

Gerhard Berz 089-3891 5290
Carlo Carraro +39-335-6170775
Jürgen Engelhard 02235-77268
Regine Günther 069-79144177
Bill Hare 030-44678765
Klaus Hasselmann 0170-9101601
Mike Hulme (excused)
Carlo Jaeger 0331-288 2601
Martin Welp 0331-288 2619

Reminder:

General information about the ECF can be found at the ECF website:

<http://www.European-Climate-Forum.net/>

Background documents and internal information (e.g. the programme of the Brussels meeting):

<http://www.european-climate-forum.net/internal/>

Your feedback on these sites is more than welcome!

The ECF Flyer is available now! I will send all members of the steering committee 20 copies. If you need more of them please let me know.

Best regards,
Martin Welp

Subject: Re: ALPIMOD-brainstorming

Date: Fri Jun 29 15:10:11 2001

Hi everyone

I have been through the ideas and offer a few (aptly non organised) comments. First Phil is away and will not be able to comment until later.

First, the project needs more explicit focus. The call will focused on natural variability . We are offering a detailed analysis of the variability of climate in the Alpine Region that focuses on CLIVAR timescales - basically very high resolution and not extending much beyond a few centuries. The project incorporates instrumental , model and palaeodata . The inter-relationships between these will be studied to gain an understanding of the nature and mechanisms of the climate variability - but is this enough. I feel it needs to be linked with a strong element of understanding the range of social/economic impacts of this variability.

Perhaps looking at aspects such as avalanches, forest damage, floods, tourism etc.? I merely put this out as a straw man . I feel the EC are putting a lot of emphasis on this aspect of research and incorporating research and researchers in these or similar areas will be a big plus.

As for the specific points in the brainstorming document -

The Dendro aspect :

I think it is essential to update the Alpine tree-ring chronologies that are available .

This is because they are a proven asset but many questions regarding tree-productivity (in relation to observed 20th century climate variability) simply can not be addressed without doing this. Many were collected over 20 years ago. The additional data would then allow new processing techniques to be employed and vital questions concerning the changing responses of tree-growth to explored. The most efficient way to do this is to involve several groups working in the Alps , (Thank you for sending the Thesis by Giorgio Strumia which is certainly a very impressive piece of work) I would think Rupert Wimmer's group and the Birmensdorf group would be ideal (Fritz Schweingruber has retired but Jan Esper has joined them in his place - I can ask them to be involved but this depends on what the group here think are the priorities and how much we see as the overall budget and institutional allocations). I should say here that I think we would require money for a single person who could , if it is agreed, work on aspects of tree-ring processing and relationships with climate in association with the other tree-ring groups, but also work with the climate and model data , especially with a view to exploring the statistical inter-relationships and dynamical associations between the different climate data sets. There is also the French tree-ring group at Marseille? Perhaps though not all need to partners - ALSO I am thinking of putting together a European Tree-ring project (or suggesting it as part of a large European integrated proxy study of Holocene variability) so if this happened there could be a link between it (involving some of the groups mentioned) and this proposal. The Swiss might be interested to produce selected site tree-ring density/updates which I think would be very valuable and I will speak to them without commitment as you ask.

As for some of the climate analysis possibilities mentioned, I very much like the ideas of detailed ,local climate comparisons with the larger CRU (and CRUder!) data. We are very interested in the association between time dependence in the relationships between circulation changes and changes in Temp. and Prec. Also changes in the nature of climate seasonality , and also extreme events (frost frequency , drought, intense rainfall). The detailed analyses of these characteristics also compliments the interpretational work on the tree-ring and glacier mass balance (and socio economic foci) data.

As for the glacier work - is not a huge effort already going into this? I think it is important but does it fit as well ? The work proposed would have to be distinguished from other ongoing efforts - though I do like the idea of linking the geomorphological evidence of past glacier change (moraines , pro-glacial sediment data?) with reconstructed glacier volume changes , where the reconstructions are based on new long instrumental data , and palaeodata (temp. and precip.) used to drive a model of the glacier volume. Our German (or Julie) colleagues can point to such work based on GCM output . My colleague here (Sarah Raper) has also done this sort of work but using a very simple model to estimate past Storglaciaren (in Sweden) volume changes and her results imply that these models must be forward driven and not based on simple regression analysis using temperature and precipitation to estimate past mass balance.

The future aspects of the discussion are important - and it is true that the previous EC call dealt with modelling and scenarios of future changes. Here, I believe the use of models should be strictly limited to understanding natural /current variability and change. There is no benefit in going for a 2 year project - I strongly urge 3. I also would find a meeting difficult. I am away from 17-29 July, and 11-25 August, and in meetings during 7-10th July and 26-31st August.

Phil will be back here next week and will no doubt comment in more detail on the instrumental analysis aspects then.

Very best wishes to all

Keith

At 05:13 PM 6/25/01 +0200, Dr. Reinhard Böhm wrote:

Friends,

As announced last Friday, we want to open a first round of brainstorming about the contents of our project. We have collected what we have received from You so far and have it mixed with our own ideas (file Brainstorming-1.doc). It does not have a nice structure and there are still a number of question marks, as You will see.

Please add things where you think something is missing and please feel free to tell us which points make no sense, or are too ambitious or simply too much work.

Please consider also the "how to do it" (state of the art methods, new approaches to solve problems, other data than those mentioned, other topics.....).

Please try also to find Your position in the project, tell us what You would prefer to do....

Please try to consider whether we would have to include other groups in terms of scientific potential and/or in terms of data (For example: Keith Briffa you mentioned Fritz Schweingruber as the leading data holder of Alpine tree-ring data. Do you think we should ask him to join us, or could You use his data also without him being a contractor of the project? In case You want him in the project could we kindly ask you to contact him, being much more familiar with him and with the tree-ring topic than we are?)

We would be glad to receive a very short answer from everybody within this week, because from June 30th to July 15th all the three of us will not be at the institute.

For more detailed considerations and answers You have more time, it would be nice to be able to study them after our return by mid of July. But please use also the possibilities to contact the other groups - the sooner we integrate to a group the better it is.

Our time-table for the rest of the time until October:

July 16th to August 14th: We are at the institute, hoping to bring the project into a near to final version what concerns the scientific content

August 15th to August 28th: Ice core conference at Kangerlussuaq (Greenland)

August 29th to September 17th: We are at the institute most of the time. We hope this will be the time to elaborate the EU-shaped complete version.

September 18th to September 22nd: Big events going on in Vienna which may cut down our time for the project (150th anniversary of our institute, Climate conference DACH-2001 (in German))

September 24th to October: Time reserved for all the things that could not be done yet in spite of our time table

Could each of You please inform us about Your time table during summer and autumn?

A question to all of You: How do You think about one 2-days meeting this Summer or in early September? What place do You prefer? If it is Austria we would have two low cost possibilities: 1): at our institute and 2) (more adventurous): At the Sonnblick-observatory (You do not have to have Alpinistic experience, we have a private cable car going up)

Some remaining questions:

Should we try a 2-years or a 3-years project?

Can everybody live with roughly 300.000 Euro (This would result into somewhere between 1.5 and two millions, which we heard is a magnitude preferred by the commission). Please consider not only the sum of money but also how to spend it and how to fill it with a reasonable equivalent in work amount.

What is your feeling about the "Climate variability atlas of the Alps"? Is it good to have one main deliverable like that or should we better produce a number of smaller

things?

One last technical remark: Please send your comments and mails not only to Vienna, but also to the other groups (or at least to those You believe would be interested in what You write). I do not think this would spoil too much our mail boxes and it has the advantage to include the whole intellectual power of our group into the construction phase of the proposal.

Looking forward to Your replies, ideas, time tables and anything else

With best regards

Reinhard

You're hardly any better, Derek: this is hardly a 'Nature' paper, is it?

You're talking about volcanic events that have a very different duration than the warming effects we're talking about. Major eruptions show up very clearly in the tree ring records going back centuries, but that's because you can pick out a one-to-three year spike rather than a prolonged cooling effect.

A rudimentary understanding of albedo is all very well, but since the radiative heat input from the Sun is still poorly understood (surprisingly) we can't deduce too much. In any case relying on mass deforestation or a prolonged series of major volcanic eruptions is hardly an attractive alternative to giving up burning what are finite

resources anyway.

Have a look at <http://www.cru.uea.ac.uk/> - particularly <http://www.cru.uea.ac.uk:80/cru/info/warming/>. We're looking at an *unprecedented* acceleration in temperature, and it's not due to a sudden lack of volcanic eruptions. Even if it turns out to be naturally-occurring, who's willing to take that chance? We should be trying to wean ourselves off of unsustainable energy generation and use anyway.

Cheers

Harry

Subject: Re: ALPIPMOD-brainstorming

Date: Tue, 03 Jul 2001 15:01:17 +0100

Dear All,

Here are a few more comments on ALPIPMOD.

Ideas are probably not very well ordered. First, you should try for a 3 year

project

and second, although here for most of the next three months (apart from odd days) I

probably

couldn't justify a meeting. I am intending on resubmitting another proposal to the October EU round. This one will involve some of the group from ADVICE. Its aim will be to develop

a daily MSLP dataset for Europe and the Atlantic (30-70N by 70W-50E). After the dataset

is produced in the first year, the second and third year will see various analyses

performed

and comparisons of several GCM runs performed at the Hadley Centre. This new project

will probably go to 2.4.1 which will be a different area from yours which will be 2.1.4.

Thus I

would hope that your proposal could be developed over email.

The above dataset would go back to 1850. This is the period which from the IMPROVE

project

is just beyond how far we think we can reliably go back with daily data. Several papers

from

the IMPROVE project (Moberg et al., 2000 in JGR and several others in press in a special

issue

of Climatic Change) have come to the about 1870 date. We have much earlier data for the 8

sites but ensuring strict homogeneity of the daily series seems doubtful for some types of

extreme measures prior to about 1870. Pressure seems better than temperature. Some sites

are better than others. Monthly is fine for all.

All the IMPROVE and ADVICE data can be used by the ALPIPMOD project. I have a summer

student updating the 51 monthly MSLP sites from ADVICE, amongst other things.

As for your ideas, I think you need some overarching theme. The atlas and CD of all

the data may be one, but it also needs to address some scientific issues which can be

shown to have relevance to the public.

I like the idea of making use of the Alpine orography looking at changes in lapse

rates and

the use of high and low elevation air pressures. The latter is a totally independent

method of

looking at the warming and can be used back to the late 18th century. The Alps have the

longest records of any mountaineous records of any region of the world. Also I am a

strong

advocate of changes in the influence of features such as the NAO (and other circulation

indicators) on surface climate. You can clearly look at these changes over the last 200

years with all the data you have.

Another important issue to a lot of climatologists is the relative surface warming

compared

to the MSU2LT data in the lower troposphere. Although this is hemispheric in extent, we

can

look with the longer Alpine records as to changes in lower level lapse rates over 200+

years.

Related to this tropical ice caps are disappearing at alarming rates in Peru, Tanzania and

in Tibet (Lonnie Thompson's work). Lonnie has calculated that the ice cap on Kilimanjaro

will not be there by 2015 at its present rate of retreat. Lonnie has some local

temperature

series for about 40 years which show a small warming yet the ice caps are going fast. Why?

These ice caps have all been cored and have ice during the MWP times yet some aren't

producing layers now !

My idea is to use the better known histories of the Alpine glaciers to see if they

are

also melting at accelerated rates than simple temperature averages would imply. Keith

mentioned the forward modelling approaches to determine positions in the past (and then

relate these to moraine termini). Do these models still function in the last 20 years?

Lonnie

thinks a lot of the tropical melting is due to sublimation, which isn't accounted for by

the

degree day models. The elevational sunshine records may be important here and with

temperature a particular season may be much more important than the other three.

All the above is just ideas, but getting all the data together (instrumental and tree

ring

as well glacier termini and mass balance) allows us to be able to model the glaciers

better than

anywhere else. All Europeans will be interested in whether Alpine glaciers are going to disappear and there will be clear impacts on biodiversity at the high elevations and tourism.

Another impact area is on the use of glacier meltwater and runoff in hydropower generation.

These are all good issues to use in the social and economic pages that need to be written.

Cheers

Phil

At 15:10 29/06/01 +0100, Keith Briffa wrote:

Hi everyone

I have been through the ideas and offer a few (aply non organised) comments. First Phil is away and will not be able to comment until later.

First, the project needs more explicit focus. The call will focused on natural variability . We are offering a detailed analysis of the variability of climate in the Alpine Region that focuses on CLIVAR timescales - basically very high resolution and not extending much beyond a few centuries. The project incorporates instrumental , model and palaeodata . The inter-relationships between these will be studied to gain an understanding of the nature and mechanisms of the climate variability - but is this enough. I feel it needs to be linked with a strong element of understanding the range of social/economic impacts of this variability.

Perhaps looking at aspects such as avalanches, forest damage, floods, tourism etc.? I merely put this out as a straw man . I feel the EC are putting a lot of emphasis on this aspect of research and incorporating research and researchers in these or similar areas will be a big plus.

As for the specific points in the brainstorming document -

The Dendro aspect :

I think it is essential to update the Alpine tree-ring chronologies that are available .

This is because they are a proven asset but many questions regarding tree-productivity (in relation to observed 20th century climate variability) simply can not be addressed without doing this. Many were collected over 20 years ago. The additional data would then allow new processing techniques to be employed and vital questions concerning the changing responses of tree-growth to explored. The most efficient way to do this is to involve several groups working in the Alps , (Thank you for sending the Thesis by Giorgio Strumia which is certainly a very impressive piece of work) I would think Rupert Wimmer's group and the Birmensdorf group would be ideal (Fritz Schweingruber has retired but Jan Esper has joined them in his place - I can ask them to be involved but this depends on what the group here think are the priorities and how much we see as the overall budget and institutional allocations). I should say here that I think we would require money for a single person who could , if it is agreed, work on aspects of tree-ring processing and relationships with climate in association with the other tree-ring groups, but also work with the climate and model data , especially with a view to exploring the statistical inter-relationships and dynamical associations between the different climate data sets. There is also the French tree-ring group at Marseille?

Perhaps though not all need to partners - ALSO I am thinking of putting together a European Tree-ring project (or suggesting it as part of a large European integrated proxy study of Holocene variability) so if this happened there could be a link between it (involving some of the groups mentioned) and this proposal. The Swiss might be interested to produce selected site tree-ring density/updates which I think would be very valuable and I will speak to them without commitment as you ask.

As for some of the climate analysis possibilities mentioned, I very much like the ideas of detailed ,local climate comparisons with the larger CRU (and CRUder!) data. We are very interested in the association between time dependence in the relationships between circulation changes and changes in Temp. and Prec. Also changes in the nature of climate seasonality , and also extreme events (frost frequency , drought, intense rainfall). The detailed analyses of these characteristics also compliments the interpretational work on the tree-ring and glacier mass balance (and socio economic foci) data.

As for the glacier work - is not a huge effort already going into this? I think it is important but does it fit as well ? The work proposed would have to be distinguished from other ongoing efforts - though I do like the idea of linking the geomorphological evidence of past glacier change (moraines , pro-glacial sediment data?) with reconstructed glacier volume changes , where the reconstructions are based on new long instrumental data , and palaeodata (temp. and precip.) used to drive a model of the glacier volume. Our German (or Julie) colleagues can point to such work based on GCM output . My colleague here (Sarah Raper) has also done this sort of work but using a very simple model to estimate past Storglaciaren (in Sweden) volume changes and her results imply that these models must be forward driven and not based on simple regression analysis using temperature and precipitation to estimate past mass balance. The future aspects of the discussion are important - and it is true that the previous EC call dealt with modelling and scenarios of future changes. Here, I believe the use of models should be strictly limited to understanding natural /current variability and

change. There is no benefit in going for a 2 year project - I strongly urge 3. I also would find a meeting difficult. I am away from 17-29 July, and 11-25 August, and in meetings during 7-10th July and 26-31st August.

Phil will be back here next week and will no doubt comment in more detail on the instrumental analysis aspects then.

Very best wishes to all

Keith

At 05:13 PM 6/25/01 +0200, Dr. Reinhard Böhm wrote:

Friends,

As announced last Friday, we want to open a first round of brainstorming about the contents of our project. We have collected what we have received from You so far and have it mixed with our own ideas (file Brainstorming-1.doc). It does not have a nice structure and there are still a number of question marks, as You will see.

Please add things where you think something is missing and please feel free to tell us which points make no sense, or are too ambitious or simply too much work.

Please consider also the "how to do it" (state of the art methods, new approaches to solve problems, other data than those mentioned, other topics.....).

Please try also to find Your position in the project, tell us what You would prefer to do....

Please try to consider whether we would have to include other groups in terms of scientific potential and/or in terms of data (For example: Keith Briffa you mentioned Fritz Schweingruber as the leading data holder of Alpine tree-ring data. Do you think we should ask him to join us, or could You use his data also without him being a contractor of the project? In case You want him in the project could we kindly ask you to contact him, being much more familiar with him and with the tree-ring topic than we are?)

We would be glad to receive a very short answer from everybody within this week, because from June 30th to July 15th all the three of us will not be at the institute.

For more detailed considerations and answers You have more time, it would be nice to be able to study them after our return by mid of July. But please use also the possibilities to contact the other groups - the sooner we integrate to a group the better it is.

Our time-table for the rest of the time until October:

July 16th to August 14th: We are at the institute, hoping to bring the project into a near to final version what concerns the scientific content

August 15th to August 28th: Ice core conference at Kangerlussuaq (Greenland)

August 29th to September 17th: We are at the institute most of the time. We hope this will be the time to elaborate the EU-shaped complete version.

September 18th to September 22nd: Big events going on in Vienna which may cut down our time for the project (150th anniversary of our institute, Climate conference DACH-2001 (in German))

September 24th to October: Time reserved for all the things that could not be done yet in spite of our time table

Could each of You please inform us about Your time table during summer and autumn?

A question to all of You: How do You think about one 2-days meeting this Summer or in early September? What place do You prefer? If it is Austria we would have two low cost possibilities: 1): at our institute and 2) (more adventurous): At the Sonnblick-observatory (You do not have to have Alpinistic experience, we have a private cable car going up)

Some remaining questions:

Should we try a 2-years or a 3-years project?

Can everybody live with roughly 300.000 Euro (This would result into somewhere between 1.5 and two millions, which we heard is a magnitude preferred by the commission). Please consider not only the sum of money but also how to spend it and how to fill it with a reasonable equivalent in work amount.

What is your feeling about the "Climate variability atlas of the Alps"? Is it good to have one main deliverable like that or should we better produce a number of smaller

things?

One last technical remark: Please send your comments and mails not only to Vienna, but also to the other groups (or at least to those You believe would be interested in what You write). I do not think this would spoil too much our mail boxes and it has the advantage to include the whole intellectual power of our group into the construction phase of the proposal.

Looking forward to Your replies, ideas, time tables and anything else

With best regards

Reinhard

HI Hans,

Yes--it was the discussion of this in the De Bilt meeting report that led me to think this was envisioned in a broadened version of the DATUN approach. I thought the idea was that you would eventually use a forward biological/physical model to scale up from a given proxy an estimate of say precipitation or temperature for an atmospheric model gridpoint and use that to nudge say the slp or 500 mb field into a particular configuration. This is clearly more ambitious than what you are doing now, and I suppose I was blurring the distinct efforts of Nanne and colleagues with that of yours and colleagues. I makes much more sense at present to only use a statistically-based upscaling of the proxy data. The other possibility remains intriguing, but we are certainly far off from doing that in my opinion as well. I'm actually quite relieved to find out that I was wrong in assuming that this is the direction the DATUN approach was going.

thanks for the clarification,

mike

Dear Friends,

A few remarks before the meeting of tonight and tomorrow,

I am sure that our meeting will make clearer the different objectives of ECF, in particular regarding the articulation between the scientific agenda and activities in direction to stakeholders and policy-makers.

I would like to stress that I will attend the ECF meeting not only in the name of the Cired, but also in view of preparing the involvement of the Institut Laplace in ECF, namely the community of climate modellers, with which we develop a long term research program. I would like to explain hereafter in a few words what should be, in my view the priorities of ECF, in terms of scientific agenda:

Given recent Ipcc experience, the first priority would be to progress in direction to integrated models. Indeed the lessons of the Ipcc are twofold:

- first the Sress scenarios confirm the possibility of generating very different emissions growth scenarios over the long run, but the consistency between the Storylines and the numerical scenarios remain uncertain; this uncertainty and vagueness reveals a more fundamental limitation of the state of the art of economic modelling over the long run, in particular to provide an explicit picture of linkages between structural changes (infrastructure transportation, urban forms that govern the energy content of final consumption, industrial structure and the so-called dematerialisation), innovation and both macro and micro economic drivers (productivity, growth and price-signals). This makes very difficult to detect where are the real bifurcations, the real policy-parameters and to make much progress in the understanding of the timing of policy responses,

- second the sections on 'damages ' have make some progress but remain weak in terms of the social and economic implications. More precisely they deal mostly with impacts on physical parameters (sea-level rise), in a few cases adress impacts on humans (tropical diseases), but all this does not give a comprehensive picture of social and economic damages (once discounted the effect of adapation),

One of the scientific objective of ECF should be to be prepared to provide in a few years for a convincing contribution in future exercises like the SRES and in the future Ipcc rounds. This passes first through two parallel efforts:

- on long term economic modelling where the limitations of existing tools are obvious despite real progress; this relates basically to three challenges:

- a macroeconomic framework insuring the consistency between prices and quantities at any point in time without necessarily resorting to the modelling tricks relying on the conventional neo-classical growth theory; these 'tricks' assume indeed perfect foresight, efficient markets and the absence of strategic or routine behaviours; New conceptual frameworks about endogenous growth theory allow for such a move, but there is a gap between advances in pure theory and empirical modelling,

- the endogeneisation of technical change and more precisely to develop this endogeneisation in such a way that the information coming from sectoral models in energy, transportation or agriculture is not lost (this comes back to the bottom-up/top-down controversy); note that one key challenge here is to progress in direction to transportation and agriculture

- an explicit treatment of expectations and uncertainty; one key issue indeed is that the stabilisation of expectations over the long run is the main driver of technical change, consumption patterns and structural adaptation.

- on 'coupling' economic and climate models: here there are two routes, either to develop coupling methods between large-scale models or to develop interface compact modules, reduced forms of large scale models. Both routes are valid, however, in the following years, to develop integrated models made up with reduced forms of larger models seems more promising; thanks to tractable and numerically controlable models, in will be easier to reveal

the key mechanisms at work and to introduce uncertainties. This will pass through progress in the representation of carbon cycle (including sequestration) in such models and, more importantly in the representation of damages and adaptation, which rises rather fundamental conceptual issues that explain what seems to be the second priority in my view.

The second priority relates to the joint question of damages and precautionary principle:

- part of the agenda is covered by Mike Hulme's paper and I will not elaborate here on other dimensions I would link to include and how to assess a cost. I will simply insist of the fact that we need to set up a taxonomy of damages in economic terms, this means as resulting not of the climate transformation per se but from the joint effect of inertia and uncertainty (to pass to Riviera to the beaches of Normandy in not a cost in itself in a world restabilized around a new climate equilibrium; what matter are the transition costs and the generated variability of climate).

Moreover I would insist for adopting deliberately a worldview because, fundamentally, climate change will generate a new human geography, and not

to be restricted to the European subcontinent,

- this should lead to develop in parallel stochastic decision modelling

tools to disentangle the many dimensions and views about the precautionary

principle and, I take some risks in saying that, in a symmetric treatment of climate damages and nuclear risks (we cannot avoid to try and put some rationale in this discussion which is one of the reason for the failure of

the EU tax in 1992 and of COP6, and which will be an 'hidden' division line

within the EU)

The third priority should be the topic 1 made by Klaus. For me the two first modelling efforts I described briefly are outmostly important to bring new insights for responding the question of the instruments.

However,

we have, before waiting for the achievement of a new generation of models (which will respond to point 2 and 3 of Klaus's paper), it matters to develop in parallel a specific programm on international coordination architecture given the failure of COP6 and the lack of understanding of economic and social implications of the selection of this architecture (coordination through prices or quantities, full agreement or partial expanding coalition, issue linkages, perceived equity etc ...). This workprogramm should build on advances on the role of economic and non economic instruments in fostering innovation, and on the distributive static and dynamic implications of such instruments.

These are very brief remarks, simply to give you some ideas about my current perspectives.

Hi Tim,

Thanks for the remarks. We can certainly spend some time talking through some of the points raised. I guess I am still finding it difficult to believe that an rbar of 0.05 has any operational significance in estimating Neff. It is kind of like doing correlations between tree rings and climate: a correlation of 0.10 may be statistically significant, but have no practical value at all for reconstruction. The same goes for an rbar of 0.05 in my mind. I agree that what I suggested (i.e. testing the individual correlations for significance and only using those above the some significance level for estimating rbar) is somewhat ad hoc and not theoretically pleasing. However, it is also true that correlations below the chosen significance threshold are "not significantly different from zero" and could be ignored in principle, just as we would do in testing variables for entry into a regression model. This would clearly muddy (a nice choice of words!) the rbar waters, I admit.

In terms of the problem I am working on (computing bootstrap confidence limits on annual values of 1205 RCS-detrended tree-ring series from 14 sites), it is hard to know what to do. Certainly, using Neff will result in almost none of the annual means being statistically significant over the past 1200 years. I don't believe that this is "true". Other highly conservative methods of testing significance result in a very high frequency of similarly negative results, i.e. the test of significance in spectral analysis that takes into account the multiplicity effect of testing all frequencies in an a posteriori way (see Mitchell et al. 1966, Climatic Change, pg. 41). If you use this correction, virtually no "significant" band-limited signals will ever be identified in paleoclimatological spectra. So, this test has very low statistical power. I think that this is the crux issue: Type-1 vs. Type-2 error in statistical hypothesis testing. The Neff correction greatly increases the probability of Type-2 error, while virtually eliminating Type-1 error. So, truth or dare.

Consider one last "thought experiment". Suppose you came to Earth from another planet to study its climate. You put out 1,000 randomly distributed

recording thermometers and measure daily temperatures for 1 Earth year. You then pick up the thermometers and return to your planet where you estimate the mean annual temperature of the Earth for that one year. How many degrees of freedom do you have? Presumably, 999. Now, suppose that you leave those same recording thermometers in place for 20 years and calculate 20 annual means. From these 20-year records, you also calculate an rbar of 0.10. How many degrees of freedom per year do you have now? 999 or 9.9? What has changed? Certainly not the observation network. Does this mean that we can just as accurately measure the Earth's mean annual temperature with only 10 randomly placed thermometers if they provide temperature records with an rbar of 0.00 over a 20 year period? I wouldn't bet on it, but your theory implies it to be so. Surely, one would have more confidence (i.e. smaller confidence intervals) in mean annual temperatures estimated from a 1000-station network.

Cheers,

Ed

>Ed,

>

>re. your recent questions about Neff and rbar etc...

>

>I've thought a bit about these kind of questions over the past few years,

>I agree with what Phil said in his reply to you. Also, your idea of
>subsampling 40% of the cores at a time sounds reasonable, though I don't
>think it would be possible to write a very elegant statistical
>justification! Anyway, I just wanted to add a couple of points to what
>Phil said:

>

>(1) Even for very low rbar, the formula certainly works for
>idealised/synthetic cases (i.e. with similar standard deviations and
>inter-series correlations etc.). For example, I just generated 1000 random
>time series (each 500 elements long) with a very weak common signal,
>resulting in rbar=0.047. n=1000 was the closest I could get to n=infinity
>without waiting for ages for the correlation matrix to be computed! The
>formula:

>

> $neff = n / (1 + [n-1]rbar)$

>

>which reduces to $neff = 1 / rbar$ for $n=infinity$ gives $neff = 20.83$. For
>such a low rbar, neff seems rather few? The mean of the variances of the

>1000 series was 1.04677. If I took the "global-mean" timeseries (i.e. the
>mean of the 1000 series, then it's variance was 0.05041. The ratio of
>these variances is 20.77 - almost the same as neff! If our expectation
>that neff should be higher than 20.83 was true, then the variance of the
>mean series should have been much lower than it was. It should be easy to
>try out similar synthetic tests with various options (e.g. shorter time
>series, sets of series with differing variances, subsets with higher common
>signal (within-site) combined with subsets with weaker common signal
>(distant sites) etc.) to test the formula further.

>
>(2) I agree that \bar{r} is computed from sample correlations rather than true
>(population) correlations.

>(a) For short overlaps, the individual correlations will rarely be
>significant. But the true correlations could be higher as well as lower,
>so \bar{r} could be an underestimate and neff could be an overestimate! Maybe
>you have even fewer than 20 degrees of freedom!

>(b) I did wonder whether the sample \bar{r} might be a biased estimate of the
>population \bar{r} , given that the uncertainty ranges surrounding individual
>correlations are asymmetric (with a wider range on the lower side than the
>higher side). But I've checked this out with synthetic data and the \bar{r}
>computed from short samples is uncertain but not biased.

>(c) Just because \bar{r} is only 0.05 does not mean that you need series 1500
>elements long to be significant - that would be the case for testing a
>single correlation coefficient. But \bar{r} is the mean of many coefficients
>(not all independent though!) so it is much easier to obtain significance.
>Not sure how you'd test for this theoretically, but a Monte Carlo test
>would work, given some assumptions about the core data. For 100 cores,
>each just 20 years long, a quick Monte Carlo test indicates that an \bar{r} of
>0.05 is indeed significant - therefore $\bar{r}=0.05$ in your case with > 100
>cores, many of which will be > 20 years long, should certainly be significant.

>

Dear Mr Hasselmann,

thanks for the draft position of the ECF. I do believe it is very good first approach to position the needs of a science-based climate policy in the future. I do particularly like the quasi-goal of a long-term 0-emission target supported by the scientific community. However, there are a few amendments I like to propose:

a) I do not agree at all that the focus on the short term "dictated by the 10 year Kyoto horizon has tended to obscure longer term issues".

In the contrary, if we were to agree on longer-term and deeper targets - what we all want I suppose - there must be a starting point somewhere in the next years. I do agree that the 1 CP targets are moderate and will be diluted by all kinds of loopholes. But given the economic and political nature of this treaty, more is/was not reachable by the international community. I prefer an unperfect agreement coevering the globe (almost!) as a starter over an perfect agreement that will never be agreed upon. And - probably more important - the recent Bonn agreement will give the signal to the main polluters that the atmosphere is not a free sewer any more. At best, they won some time - but the ultimate message is, that the train towards deeper targets has started. This may impact future industrial investment and legislative decision making much deeper than the targets of the 1 CP itself as it provides some basic certainty. Having said this, the next important discussion round on a political level will resume about "adequacy of commitments" of the next CPs. that is the build-in logic of both the treaty and the Convention. Here countries will start to address targets for 2013-2018. Thus, there is an approach to the long-term issues. It is a transient process over time. And, please believe me, almost everyone I talked to in the past who complained about the "short-term" focus of the treaty as opposed to a long-term global strategy had not in mind to strengthen environmental effectiveness - these voices mostly reflected the desire to fully delay any early action after all. And without early action and without short term focus we will never get to the longer-term targets.

In short, I believe, a scientific approach should foster the architecture of the KP and that of the Convention and the need for further target-setting processes in the future by all parties - and that is intrinsincally embedded in the process.

In that respect, it is probably scientifically correct to state that the "Kyoto reductions have negligible impacts on global warming" but it would be politically naive to conclude that this means Kyoto is only "symbolic". It is much more.

b) I have problems with the focus on solar as the sole beneficiary of a 0-emission society. Still, I still like to focus on those measures that are not implemented yet and can provide the bulk of future emissions reductions mostly cost-effectively - that is energy efficiency in its various forms and various applications. And renewables are those who benefit most from energy efficiency as each renewable kWh provides more service, km or goods.

Generally, I like a broader approach to renewables. It is not "one takes it all" solar what will save the world from climate change. We need many forms of renewables according to the cultural, political and economical circumstances in the various regions. In some it may be solar thermal power or PV, in others it is off-shore wind, and in many rural areas it may be biomass or geo-thermal energy. And let us not forget the challenge of producing hydrogen from renewable sources as another ultimate fuel.

c) How do we deal with equity? I believe it has to be addressed in one way or the other - and I mean much more than the usual GHG emissions per capita approach. This would include compensation/adaptation funding for poor and vulnerable developing countries - but also how to deal with targets for (certain) developing countries in the next CPs.

best regards
Stephan Singer

>Dear Stephan (I suggest we use the anglo-saxon first-name form, coupled
>with "Sie" if we slip into German)

I agree with all of your points and hope you will contribute to finding
the
right language in our position paper to reflect both the need for long-
term
goals and the value of at least starting off with something one can build
upon. One of my motives was to help keep the door open for those who wish
to join the process later without too much embarrassment. I also agree
that
we need to investigate all technological options. I am certainly not an
expert in this field and am willing to learn from those who see more
Global
Mitigation Potential in some of the currently proposed technologies than
I do.

With best regards
Klaus

Been away on holiday - is this still relevant?

Mike

At 10:10 03/08/01 +0000, you wrote:

Dear Sirs:

The Ecologist, a London-based internationally recognized environmental magazine, will be publishing a Special Edition on Climate Change in September. For this edition, we believe it would be extremely useful to gather the opinions of the top climatologists on an issue for which there is growing interest by those concerned with climate change.

This issue is addressed in Article II of the United Nations Framework Convention on Climate Change, which states:

"The ultimate objective of this Convention and any related legal instruments that the Conference of the Parties may adopt is to achieve, in accordance with the relevant provisions of the Convention, stabilization of greenhouse gas concentrations in the atmosphere at a level that would prevent dangerous anthropogenic interference with the climate system. Such a level should be achieved within a time-frame sufficient to allow ecosystems to adapt naturally to climate change, to ensure that food production is not threatened and to enable economic development to proceed in a sustainable manner."

Furthermore, the need to address the issue of atmospheric concentrations was recently reaffirmed by Michael Zammit Cutajar, Executive Secretary of the UNFCCC, who stated at the closing session of the IGBP in Amsterdam on 13 July 2001,

"I believe that the political process on climate change would be greatly assisted by agreement on a target for atmospheric concentrations, at least an intermediate target. This would give a sense of where the whole international community should be heading and a basis for apportioning responsibility for getting there."

We would be very appreciative if you would send a return email with your response to the following questions for publication in The Ecologist Special Edition on Climate Change.

-At what levels do you think we should aim to stabilize carbon dioxide concentrations in the atmosphere and why?

I do not believe we have any sure basis for establishing what a 'non-dangerous' level should be. This is so for several reasons:

- what is 'dangerous' depends on what measures are taken to adapt to climate change.

550ppm may be 'safe' in one assumed future world but 'dangerous' in another.

- the concept of 'danger' is not one that science can pronounce on. Such a level has to be negotiated via a social and political process. This negotiation has also to take place in the context of other risks that society is exposed to, i.e., we may be prepared to run a higher risk with climate change if it means we can divert greater resources to reducing global poverty.

- the basis for establishing 'danger' is contested. One could argue that 'dangerous' climate change is change in climate that leads to the death of just *one* person; or argue that some benefit/cost ratio should be used; or argue that if a sovereign state is extinguished (e.g. a Pacific atoll nation) then that is the definition of 'dangerous'.

Thus you can see that I do not believe we can arbitrarily choose 550ppm or 650ppm, as done by many scientific pronouncements (including the IPCC and others), and claim that is our target. This can only be done by using the instruments of social and political discourse on an international scale.

What we can say is that the higher the concentration of CO₂ reached the greater the likely risks associated with that concentration will be. But this is a relative argument, not an absolute one.

-What does that level equate to in terms of percentages of emissions reductions and by what date should we aim to reach that level?

So you see this second question I cannot answer. What we need to be doing, while we debate the first question, is to put in place measures/mechanisms/processes that will now, and in the future, give us greater flexibility of choice about different energy systems that have different carbon ratings. The process is more important than the targets, as the Kyoto negotiations have amply demonstrated.

In 10 years time, what we regard as 'dangerous' climate change will be very different from today - and different again in the year 2020. We therefore need an emissions reduction strategy that is flexible and reflexive to the changing demands of society.

We are aware that there is currently no consensus within the scientific community on what an appropriate level for atmospheric concentrations is.

Indeed not - and there never can be. This question is not appropriately answered by science - it has to be answered by society! This is a very important point to get across.

Our aim in this endeavour is to share with our readers the values considered relevant to this debate to illustrate why a consensus is difficult to achieve.

Exactly so - and in the end it is a matter of risk assessment and risk management. And with most matters of risk, it is the perception by different individuals that matters more than any quasi-objective estimate of risk. Temperamentally I take more risks than does my wife - my concept of dangerous climate change is likely therefore to be quite different from hers. Writ large and across the nations of the world, this is the problem of climate change management.

Thank you in advance for your consideration.

Sincerely,
Matilda Lee

Subject: Re: TGCIA scenario recommendations

Date: Mon, 27 Aug 2001 11:39:11 +0200

Cc: m.hulme@uea.ac.uk, parryml@aol.com, Rob Swart <Rob.Swart@rivm.nl>, steve smith <ssmith@pnl.gov>, s.raper@uea.ac.uk, Tsuneyuki MORITA <t-morita@nies.go.jp>, tim.carter@fmi.fi

Dear Tom,

Thanks for your message and papers. The problem is clearly one of the science-policy interface. If science cannot demonstrate that it makes a difference in terms of avoided climate change and impacts if GHG concentrations are stabilised, why bother? Currently a Danish guy, Björn Lomborg, is making the headlines again (Guardian, New York Times, Economist), TV programmes, etc.) telling the public (and policymakers) not only that there aren't any environmental problems, but also, even if climate change may be real, it does not make any sense at all to do something about it, since efforts to control GHG emissions are expensive and the mitigation would not make any difference at all anyway in terms of avoiding negative consequences. Very popular message. Now clearly, scientists should clearly explain what they can say about this issue. My expectation would indeed be that comparing climate changes resulting from reference cases and from stabilization cases would not be distinguishable until well into the 2nd half of the century (like in the GRL paper), but if this is so, so be it. 2050 seems a lot closer now in 2001 (2050 is THIS century and our childrens' lifetime) than it was in 1999 (when 2050 was something of the next century and some abstract next generations). It is a matter of communication skills to get the message across about the long timescales and inertia of the systems involved, and the difficulty of identifying the climate change signal in the noise of natural variability. I would be curious what your opinion is about the UK work of Nigel Arnell, Martin Parry, John Mitchell and others, analysing the (significant) avoided impacts of 550 stabilisation from an IS98a reference. Another strategy of concerned scientists may be not to do these analyses at all in order to avoid a possible result that the differences between reference and stabilisation can not be demonstrated in a scientifically credible and unambiguous way and hence climate policy action may be obstructed. To me, this does not seem to be the honest way to go.

I am not sure what this all implies for the planned recommended stabilization runs. Your points about the climate sensitivity and non-CO2 gases are well taken. I am not sure the sulfur emissions in the proposed post-SRES scenarios would make a lot of difference, since already in the SRES base cases sulfur emissions are pretty low, and these would only be slightly different (usually lower) in the stabilisation cases. You suggest "carefully constructed idealized scenarios". Do you mean carefully constructed from the climate system point of view in order to get "distinguishable results", or carefully constructed from the socio-economic

point of view so as to analyse real-world consistent and plausible futures (the latter is what Morita's exercise tried to achieve)? My answer would be: both.

I'd like to reflect a little bit more on this and since I am a scenario expert rather than a climate expert, await reactions from people more expert in the area of climate modelling, like Sarah, Mike and Tim, and Martin himself as chair of the TG CIA.

Thanks again,

Rob

Subject: Re: TG CIA scenario recommendations

Rob and others,

The key thing with doing stabilization runs with AOGCMs is (as Rob says) that the different cases "would have to be distinguishable from one another". This is the crux of the problem (in fact, it is a non-trivial problem even to define what is meant by "distinguishable from one another").

A few years ago we decided to try to do some matched no-climate-policy and (550ppm) stabilization runs where the two scenarios had some semblance of realism. (It turns out that the only similar work is that done by the Hadley Ctr, but the scenarios they used are highly idealized.) Our runs were also idealized in that we only changed CO2 -- in the best scientific tradition of changing only one thing at a time to assess sensitivities. The first results of our exercise (using CSM) are in Dai et al., J. Climate 14, 485-519, 2000. A number of things were clear from this. First, one cannot tell much from single realizations of the two cases -- ensemble runs are essential. Second, as we already knew

from running simple models, the no-policy and stabilization runs diverge only slowly. Even after 50 years, the two are only just distinguishable at the global-mean level; so, clearly, differences at the regional level (especially for precipitation) would not be detectible above the noise of natural variability.

So our next step was to do ensembles of 5, this time using PCM instead of CSM (this paper is in press in BAMS -- for a pdf preprint, look at www.cgd.ucar.edu/cas/adai/). Even then, for ensemble means, the separation between the no-policy and stabilization cases is slow. So I devised an extended no-policy case out to 2200 (50 years beyond where the CO2 level stabilizes in the stabilization run), and we extended some of the runs out to 2200. This work is in press in GRL (and downloadable from the above site). Additional important results come from these experiments. One important result is that, even for precipitation, the *patterns* of change are not detectibly different between the no-policy and stabilization runs. A second important result is that, for most of the world the intra-ensemble differences are similar to or greater than the underlying signals of change. Distinguishing the no-policy and stabilization runs therefore presents a much greater challenge than any of you probably realize.

There are two issues to keep in mind, however. The first is that PCM and CSM have quite low climate sensitivities. So, will things be different if one used a more sensitive model? I suspect not in any major way. The reason is because inter-annual variability tends to be higher in more sensitive models, so the signal-to-noise ratio may not change much. This also applies to the intra-ensemble noise, since the root cause of these intra-ensemble differences is the internal variability of the model.

The second issue is that we have only changed CO2 in our experiments. We know that attempts to stabilize CO2 via emissions reductions also affect SO2 emissions -- so perhaps the no-policy and stabilization cases might be more distinguishable if one accounted for these concomitant SO2 effects? I have addressed this issue at the global-mean level in a paper on stabilization that I will attach to this email. (A more extensive analysis is in another paper, with Steve Smith as my co-author, that I am not ready to share with anyone just yet.) My judgment, as someone with quite a lot of experience in this area, is that having full spatial details will not make the problem any easier; since, as the spatial scale is reduced so the noise increases.

My recommendation from all this is that, first, you read the attached paper (and I would welcome feedback on this) and the three above-mentioned Dai et al. paper. Then, you might want to re-consider what your strategy should be. In my view, I do not think we as a community are at the stage where we can blindly develop paired no-policy and stabilization scenarios and simply feed them into AOGCMs to see the consequences. I believe that carefully constructed idealized scenarios (perhaps based on what Morita is doing) will provide much more useful

information. You are already probably well aware of the need to do ensemble runs, and I don't need to remind you how computationally expensive this can be.

I hope these comments, and the papers, are useful. I'm sorry that it is impossible for me to come to the Barbados meeting, but I am willing to help in any way that I can.

Best wishes (and good luck), Tom.

Subject: Re: ECF position paper
Date: Fri Aug 31 17:37:14 2001

Klaus,

A few belated comments on your 1st draft which is looking promising:

a. we need to be careful about using concepts/terms such as 'unacceptable' global warming.

As I think Richard Tol says, we do not have any sound basis for determining what

constitutes 'dangerous' climate change. Is it one life lost? a nation-state inundated?

or some more utilitarian exceedance of a benefit/cost ratio? Does every citizen on the

planet have a vote or just each government? We should draw attention to the rather flimsy

basis upon which notions of safe or dangerous, tolerable or unacceptable climate change are

debated. In the end of course there are lots of things we may view as 'unacceptable' (war

for example), yet they happen and we survive. I think this is an area rich for research

and we could draw out some of the dimensions.

b. later on you use the idea of balancing abatements costs vs. the risks of climate

change. I think we need to use the language of risk here and to draw upon insights

developed by risk analysts (academic and professionals) about how we frame the climate

change problem in risk terms. The differential perceptions of risks, inc. climate ones,

therefore becomes central in addressing point a.

c. the proposed ECF project on changes in extreme weather is of course a necessary first

step towards the quantification of climate risks. This should be one of the justifications

for work in this area. It is also the case that better understanding of these changes will

yield insights into how adaptation does or should proceed, at both environmental systems

and institutional systems levels.

d. re. nuclear energy in a climate protection portfolio, the ECF should be bold and should

question and expose assumptions made on both sides of the debate about the up and

down-sides of this technology. It is rising higher on the UK agenda and there will be some challenging times ahead in this country about its rightful place and role.

I look forward to seeing the second draft,

Mike

At 14:24 11/08/01 +0200, Klaus Hasselmann wrote:

Dear colleague:

I was requested on the 6.August telephone conference by the ECF skeleton board and the

members of the former ECF steering committee to coordinate the writing of an ECF position

paper, as agreed upon at the ECF meeting in Brussels on July 12.

It was proposed that we complete the position paper and present it to the press about a

week in advance of the Marrakech COP 7 meeting in November this year.

I suggest the following timetable:

1) preliminary agreement on the structure and contents of the paper by the end of this

month,

2) production of first draft in September,

3) detailed discussion of first draft on 2nd October in Potsdam (an additional day ahead

of the 3-4.October ECF meeting, which was proposed on 6.August to discuss the details of

the various projects agreed upon at the Brussels meeting)

4) completion of the paper in October.

5) November: presentation of the paper

I would hope that apart from the 2nd October meeting we can achieve our task by e-mail.

But a meeting may be necessary in September. If so, we should try to combine it with one

of the other project meetings that will be taking place in September.

Everybody is invited to participate. Please feel free to copy this mail to other ECF

members or potential members who I may have missed.

It has been suggested that the position paper should be short, about 5 pages, plus some

appendices if necessary. To get the discussion going, I propose the attached structure as

straw man. Please note that many of the points I have listed are my own views, and I

will be happy to - and expect to - modify them based on your responses.

With best regards

Klaus

Hi Ed,

Just to reiterate one more key point--Superimposing the two series and their uncertainties is not the whole story (although it is a definite improvement over just showing the two reconstructions on top of each other w/ know assessment of uncertainty). However, doing the above still only poses the question:

apple +/- [uncertainty in apple] =? orange +/- [uncertainty in orange]

As we discussed in a previous email exchange (based on the correlations you calculated between instrumental series w/ the trend removed) , the two reconstructions should probably only share about 60% or so variance in common in the best case scenario, where there is no uncertainty at all, owing simply to the differing target regions/season...

So we need to be very careful w/ the following statement which you made in your previous email:

"If so, this would not mean that the series are not significantly different from each other. One can't dismiss the highly systematic differences at multi-centennial timescales quite so easily."

I'm not sure you can justify that statement based on sound statistical reasoning!

I agree w/ your following statement "Why these differences are there is the crux question."

However,I hope the discussion will accurately reflect the fact that the leading hypotheses to be rejected in answering that question are 1) random uncertainty in the two series owing to differing data quality and sampling, etc. can explain the difference and 2) systematic differences owing to differing target region and seasonality can explain any residual differences after (1).

That may be a tough standard to beat, but it *is* the approach that Tom, Phil, Keith, and I have all been taking in addressing the issue of whether our different reconstructions are or are not inconsistent and the conclusion has in general been (see e.g. IPCC which was really a consensus of many of us, though admittedly only I was a lead author) that, despite notable differences in the low-frequency variability, the different reconstructions probably cannot be considered inconsistent given the uncertainties and differences in seasonality/spatial sampling. I have a hard time understanding why the same standard should not be applied to comparisons w/ your current reconstruction?

Does your RCS reconstruction really not fall in the mix of all the other reconstructions? Is it truly an outlier w/ respect to Phil's, Tom's, MBH, and other existing N. hem reconstructions that are based on different seasonality and regional sampling???

We've probably had enough discussion now on this point, so I'll leave it to you to discuss the results in the way you see most fit, but I really hope you take the above points into account, in fairness to the previous work...

I look forward to seeing the final manuscript in one form or another, in any case,

cheers,

mike

Dear Ed - Didn't Keith Briffa also come up with a more marked LIA than MBH99 in his age-band work? If this turns out to be right, it should eventually be easier to find the sources of the differences between the reconstructions, just by virtue of there being not only many more tree-ring data for that period, but also more other, data, such as documentary. Cheers, Malcolm

Date: Mon, 10 Sep 2001 16:45:18 -0400

Hi Keith,

You probably haven't seen the newest version, which has not yet been submitted, but I CLEARLY state that several of the data sets/sites used in the paper have been used before and I reference all of the relevant papers. I never implied anywhere that this was the first successful use of RCS. I also reference your Quat. Sci. Rev. paper and your Age Banding paper. I also state in the concluding section that what has been shown is not new, but it is somewhat novel (the separation of the data into RC curve classes and the regionalization of the data on the scale described) and informative. I stand by that completely. So, the version I am working on covers (hopefully) some of your concerns/complaints. I will do my best to be "fair" before I finally submit it. However, this is a Report to Science (~2500 word limit), so I can't do the kind of review of the literature and detailed discussion of results that would be possible in more normal size papers.

Sorry for sounding a bit testy here. I've been fielding a whole raft of questions, comments, and criticisms from Mike Mann, Tom Crowley, and Malcolm Hughes. Some of them useful, many of them tiresome or besides the point. I never wanted to get involved in this quixotic game of producing the next great NH temperature reconstruction because of the professional politics and sensitivities involved. All I wanted to do was demonstrate with Jan that Broecker was wrong, something that you have obviously done a few times before but in journals that Broecker and others don't follow closely (I guess. I should also say that the amount of ignorance about tree rings in the global change/paleo/modeling community is staggering given what has been published. Like it or not, they simply don't read our papers.). In so doing, it seemed reasonable to compare the RCS chronology against the hockey stick because that is the series that Broecker was railing against. That is why I didn't bother to compare the series against all the other records produced by you, Phil, and others. Jan originally did that, but I chose to restrict the comparison to tighten the focus of the paper. More reference to your results is clearly justified, so maybe I was wrong here.

This all reinforces my determination to leave this NH/global temperature reconstruction junk behind me once I get this paper submitted. It's not

worth the aggravation. However, the paper is something that I need to do for Jan. And I still think it is a good paper.

Cheers,

Ed

>What I really mean is that you have written this paper implying that you
>are getting low-frequency NH temperatures out of tree-ring data for the

I still believe you are not showing sufficient comparisons with series besides the MBH ; necessary to demonstrate the true extent of "new" information in this work. At the very least this needs to acknowledge that other (and other tree-ring-based) series are out there , that use at least some of the data you employ , and use the RCS method to process may of their constituent series - i.e. the Northern chronology series shown in my QSR paper. What is similar and what is different in your series and this one? You give the impression here that you are using the RCS and new data to demonstrate the possibility of getting more low frequency signal from tree-ring data - but then you base this on a comparison with MBH only. Surely what is needed here is to establish WHY MBH don't get as much LIA for example . By not showing that other tree-ring data that have also shown a LIA , and not exploring why MBH does not (despite using some of the same -and note -already RCS standardised data) is perhaps confusing rather than clarifying the issue. When we discussed this here, I also suggested the need to show separate "north" and more "south" curves ,separated in your data set, to try to get at least some handle on the independent expression of the centennial trends in a region south of the over-exploited northern network . At the very least it should be clearly stated that many of the site data used here and in previous work (see our Science perspectives piece) are common and other series already produce more low-frequency signal than is implied in MBH . Sorry for this rushed comment but I wanted to get this point over as we had talked about it before but you don't seem to have taken it on board.

cheers

Keith

At 02:51 PM 9/10/01 -0400, Ed Cook wrote:

Hi Mike et al.,

Okay, here is an overlay plot of MBH vs. RCS, with RCS scaled to the 1900-1977 period of MBH, and with 95% confidence limits. This has been done for the 40-yr low-pass RCS data to be consistent with the low-pass MBH series you sent me. The 95% confidence limits of the RCS are also scaled appropriately. Since correlations with both instrumental and MBH are $O(0.95)$ after even 20-year smoothing because of the trend, the RCS limits are effectively based on the bootstrap 95% limits of the 14 chronologies. Assuming that the original RCS C.I.s are reasonably accurate (which I think they are), what is apparent (to me anyway) is that the confidence limits of MBH are uniformly narrower after AD 1600. Prior to that, they are comparable to RCS back to ca. AD 1200 where RCS C.I.s get bigger. Of course this is an odd comparison because the confidence limits are not derived the same way. However, I do think that they are somewhat informative nonetheless. What is also apparent is the much great amplitude of variability in the RCS estimates. This is consistent with the understanding that extratropical temperatures are more variable than tropical temperatures, which supports the idea that the MBH record does have more tropical temperature information in it. The other interesting thing about expressing the RCS data this way and overlaying it on MBH is the appearance that MBH is missing the LIA rather than the MWP, at least on multi-centennial timescales. This turns some of Broecker's criticism of the "hockey stick" on its head. I'm not sure where all this leads.

Any comments and further suggestions are welcome as long as they come in by tomorrow. I am definitely submitting the paper within a day or two.

Cheers,
Ed

Dear Keith,
below is the list of the Ekaterinburg team members with brief description.

=====

Stepan G. Shiyatov, Prof., Dr., head of the Laboratory of Dendrochronology, leader of Ekaterinburg team, took part in collecting subfossil wood in the Yamal Peninsula, cross-dating ring-width series, developing and analysing the multimillennial ring-width chronology. He has also carried out the work on evaluation of changes in composition and structure of forest-tundra ecosystems in Polar Urals.

Rashit M. Hantemirov, Dr., took part in collecting subfossil wood in the Yamal Peninsula, cross-dating ring-width series, developing and analysing the multimillennial ring-width chronology. He has also developed and analysed juniper chronology in Polar Urals.

Valery S. Mazepa, Dr., took part in treatment of individual ring-width series and analysing of the Yamal long chronology. He has also carried out the work on estimating of changes in woody biomass in Polar Urals.

Alexander Yu. Surkov, technician, took part in collecting, preparing and measuring the subfossil wood from Yamal Peninsula

Dear Simon, Andy,

Many thanks for agreeing to each give an informal presentation to the Steering Committee on the first afternoon of the meeting.

As I mentioned on the phone, what I'm after is for each of you to look at the Abrupt proposal and Prescient proposal/draft-science plan (attached as WORD documents), stand well back, and put forward some ideas for how one might combine them into a single coherent programme. The intention is to lay the foundation for some discussion, both Monday afternoon and evening, in advance of the formal Steering Committee meeting item that will deal with developing a single science plan. All SC members will have the attached documents in their papers.

I'll summarise the few constraints we have at the start of the Monday session, so you won't have to revisit the history; by the time we get to you, all will know that we have

the task of coming up with a single plan, and the events leading up to that circumstance.

The constraints as I see them are:

The Rapid Climate Change programme has a budget of £20m. The Abrupt proposal was written to £16.9m, and the STB decided to invest £17.0m in thermohaline-related rapid climate change. This proposal contained both palaeo and modelling components (as well as modern observational/process work), and a strong complementarity and close working relationship with Prescient was always envisaged by the writers. The Prescient proposal was written to £8m, and the Prescient draft science plan (following reduced award) was written to £4.5m. The STB did not have a discussion about how the science of the two programmes should be combined, but the nature and chronology of events/discussions imply that the STB decision to spend £17m on thermohaline-related work should be respected. I do not see that this has to be translated as an inexorable shackling of the £4.5m Prescient science aims, given that a good fraction of the Prescient draft science plan seems to be potentially relevant to thermohaline-related climate change, and that there is notionally £3m of the £20m that is not tied to thermohaline-related work, and there is a strong palaeo/modelling element to Abrupt.

So much for constraints. I do not want to give the impression that we are after a ring-fencing of Prescient and Abrupt monies and aims within Rapid. I would hope that there is scope for a much more integrated (in the sense of both palaeo/modern and obs/model) and coherent programme than that. One potential conflict, in the modelling context, seems to be the apparently regional approach of Abrupt cf the global approach of Prescient. I suspect (but may be wrong) that there is a scientific debate to be had as to whether an Atlantic-centric approach is sufficient to consider thermohaline-related climate change over NW Europe, or whether a more global treatment is required.

On practicalities, I've got you down for 20 minutes each, and have set aside half an hour for discussion straight afterwards. Please let Catrin Yeomans (cvy@nerc.ac.uk) know your audio-visual needs.

Get back to me if you need further clarification.

All the best,

Phil

Subject: TERI launches TerraGreen, an e-magazine on the environment
Date: Wed, 28 Nov 2001 16:40:00 +0530

TERI is proud to announce the launch of TerraGreen (<http://www.teriin.org/terragreen/>), an e-magazine that will bring you news about energy, environment and sustainable development from India, once every two weeks.

TerraGreen was formally launched on Wednesday, November 28, 2001 by Mr. C. M. Vasudev, Secretary, Department of Economic Affairs, Government of India in New Delhi.

You are receiving TerraGreen because you have shown interest in TERI's research, multifarious activities or numerous publications over the years. Your address is saved in TERI's central database of e-mail addresses. If you should prefer not to receive this e-mail in future, please let us know. To do this, please scroll down to the end of this e-mail.

TERRAGREEN
News to Save the Earth

Issue 1, 15-30 November, 2001

Letter from the editor

Here is the first issue of TerraGreen, an e-magazine that will bring to you the most significant shakeouts in India's energy, environment and sustainable development scenarios. For concerned individuals across the world looking for reliable news and information in these fields from India has often been an uphill task. TERI has worked for over quarter of a century to disseminate information from these very fields. Taking that mandate forward, TerraGreen will bring you analytical, unbiased and straightforward reportage. In the wilderness of the Internet you will soon learn to rely on TerraGreen for news, views and information. So, welcome to the wilderness. Enjoy.

For full text click on:
<http://www.teriin.org/terragreen/issue1/letter.htm>

News of the fortnight

What's happening in our green horizons and elsewhere? TerraGreen's news updates bring you the latest in environment news.

This issue's headlines

Pepper and people power

Periyar Tiger Reserve, Kerala- The India Ecodevelopment Project brings a much-needed economic fillip to the lives of Mannan and Paliyan tribals through pepper cooperatives. Find out how it all happened at <http://www.teriin.org/terragreen/issuel/news.htm#pepper>

Sunny through the clouds

New Delhi- Anybody for the sun? Soft loans for setting up solar water heaters in group housing societies from IREDA. Visit <http://www.teriin.org/terragreen/issuel/news.htm#sunny> to also find out about sun-powered electricity in the high, cold reaches of the Himalayas, for villagers in Leh and Kargil.

Of Birds and War

Afghanistan- The terror of war and bombings in Afghanistan is spreading far. So hangs the fate of India's winged migratory friends -- the Siberian crane, shoveller ducks, the crested poacher and Arctic tern, to name a few. At <http://www.teriin.org/terragreen/issuel/news.htm#birds> read about these avian anxieties.

The Long Story

Let the Gentle Giants Be

Veraval, Gujarat- Fahmeeda Hanfee's first-hand report on the huge but vulnerable whale shark, and on a milestone that is something of a first in the official protection for marine life in India. Hanfee analyses the pros and cons at <http://www.teriin.org/terragreen/issuel/feature.htm#f1>

The Water Harvest

Kalakhoot-Madhya Pradesh, Sangani-Gujarat- Arnab Ray Ghatak's inspiring report of villagers (<http://www.teriin.org/terragreen/issuel/feature.htm#f2>) who looked beyond governmental apathy to drill water from parched lands on their own and are now reaping a golden harvest.

In Conversation

At a time when a lot of people across India are grappling with power shortages, Mr Suresh P. Prabhu, Union Minister for Power, talks to TerraGreen's executive editor in a one-on-one. <http://www.teriin.org/terragreen/issuel/interview.htm>

Centrepiece

No one Need Go Hungry

Dr. L. C. Jain, Chairman, Industrial Development Services, economist and Gandhian, Dr L C Jain, unfolds a simple blueprint to change the bizarre food security situation India faces today - of rotting foodgrains and starvation deaths. Read more about Jain's views at <http://www.teriin.org/terragreen/issuel/essay.htm>. He laments that if Gandhi were to be around today and learnt of this cruel irony, he would invite an assassin to end his life.

Reviews

Get the latest on your green reads. This week: Subhadra Menon reviews Brenda Cranney's *The Mountain Women of Himachal Pradesh*. Plus more short reviews at <http://www.teriin.org/terragreen/issuel/reviews.htm>

People in Action

Ever wondered how to reach people working at the grass-roots? To be able to make a difference? Let nothing stop you, contact them to work alongside, or just to help. Go to: <http://www.teriin.org/terragreen/issuel/people.htm>

Forthcoming Events

Check out our green calendar <http://www.teriin.org/terragreen/issuel/events.htm> for the fortnight.

Factfile

At <http://www.teriin.org/terragreen/issuel/facts.htm> check out some interesting facts about the environment around us.

CONTACT

Reach the executive editor of TerraGreen at <http://www.teriin.org/terragreen/contact.htm>

FEEDBACK

Need to reach us at TerraGreen with comments or suggestions? The second issue of TerraGreen is in the pipeline, do mail us at terragreen@teri.res.in or please fill the form at <http://www.teriin.org/terragreen/feedback.htm>

SUBSCRIBE WITH US

You are currently subscribed to TerraGreen. If you want to notify a change of address please write in at terragreen@teri.res.in or please fill the subscription form at <http://www.teriin.org/terragreen/subscribe.htm>. While we hope you find TerraGreen useful, to unsubscribe please send us a message at the same e-mail address with 'Unsubscribe' written in the subject line.

ABOUT US

If you want to know more about the TerraGreen team, go to <http://www.teriin.org/terragreen/about.htm>

At 00:03 12/12/01, you wrote:

Hi Tim and Phil,
I'm afraid I missed their deadline -- I'm presenting at the Royal Society meeting on IPCC tomorrow, and that had to take priority. If Simon is interested enough to bend some rules quietly, I could certainly get him an outline proposal by Friday, but if not, it'll have to wait until their next call. It's frustrating, but it can't be helped. NERC just have too many calls. As Simon points out, the Tyndall Centre's style may be a more top-down, regulatory approach anyway, and good luck to them. Politically negotiated emission targets may work, but I have to confess to having doubts. Perhaps I have spent too much time talking to Dick Lindzen to believe in central planning any more.

Myles, by "Simon" do you mean Simon Shackley? I don't think he'd be able to bend the rules since the proposals have to go direct to the Tyndall Centre's administrator. As you say, they are being more directive (is that a word?) in what they want this time round, and since your idea isn't central to what they think they want I doubt whether they'd be prepared to bend the rules. Hope the Roy Soc goes well - I hear they're charging 100 quid to listen to you - a bargain!

Ed (and Jan)

Frankly I am a bit surprised at your and Jan's response to my letter.

I thought I had explained clearly what I was writing to Science and did only that. After some not too little experience in reviewing for Science and Nature , I returned what I considered to be a very positive response, one which I knew Science would interpret as a call to publish important results. This is precisely what they have done and no more could have been expected. As to the sentiments and opinions expressed , they are objective and , in my opinion still correct. They are to be interpreted as a request for re-thinking the logic and rationale of the presentation. I do not see why they require more than some re-phrasing. Though I will admit that they ask for some minor (entirely justifiable) work to include the correlations with summer seasonal data. I simply would not like to see you write a paper that puts out a confused message with regard to the global warming debate , leaving ambiguity as to your opinion on the validity of the Mann curve and implying that your series is a annual record , when I do not believe that you think it is. To get Science to consider a rewrite is surely what you would have hoped for , and satisfying my remarks , in small or large measure , will not be the determinant in getting this published. Indeed , it may well be that the tone of my letter could have convinced them that this was important work that should be published (though with some provisos) despite what other reviewers may have thought. What did the other reviewers say?

If you think I was too negative then I am sorry that we don't agree entirely - but that at least is the normal !

I would not like this affair to ruin my Christmas , as it surely will if it is the cause of our falling out . As for your message Jan , I prefer to think you were trying to calm troubled waters , though you seem peculiarly adept at doing the opposite where I am concerned, I prefer to ignore the remark about "not wanting to let this curve into Science" (a response might only injure the prospects of any further collaboration) but I will say that it goes without saying that Ed can have his opinion , just as even I can have. I would never consider myself stupid enough to imagine I could ever influence your response to Science by anything other than reasoned argument. If this is not accepted then ,at least Ed I am sure knows that, I would not let this stand in the way of this paper.

Ed, I am sorry to hear about your condition and I do know how debilitating it is. Useless as it is , you have all my sympathy and best wishes for a rapid recovery.

I am likely also guilty of short temper and extreme frustration at the moment because of conflicts between family and work , both sides demanding more time and both being increasingly ill served by me. Somewhere in the middle I feel increasingly suffocated of late and in moments of sane reflection can see that much of the trouble could perhaps be

lessened if one had time to be more considered in ones actions - but the moments of quiet reflection are invariably harder to find.

I am totally confident that after a day's rephrasing this paper can go back and be publishable to my satisfaction by Science. I am equally confident that this interchange was a waste of yours and my time . To the extent that I am culpable , I am truly sorry.

Keith

At 09:23 AM 12/17/01 -0500, you wrote:

Hi Keith,

First, I need to apologize a bit for what I wrote to you. It was a bit over the top and came out during some serious physical discomfort that I am experiencing now from a bout of shingles(? I'll find out from the doctor today). It is all rather painful and depressing. So while I still think that we have very real differences of opinion on the paper, I would hope that we can accept at least some of these differences as part of the scientific debate process and not let it affect us negatively or personally. Paul Krusic came by yesterday and brought with him several parcels from the lab, including the paper from Science. The editor will not accept the paper as submitted, but will consider it after revision. Obviously, this is as good as we should have expected. I will do whatever I can to satisfy the reviewers comments, including yours, but probably can not rewrite it in a way that will satisfy all of your concerns. At that point, it will be up to Science to decide how to proceed.

Regards,

Ed

Date: Tue Jan 22 15:42:27 2002

Stepan

I have the form , but it is not clear . Where I think I sign (page 1 bottom. under co-ordinator) it says I have to prove my identity in Brussels?

I will phone them to ask before sending the form back. Will Eugene need a similar signature?

Keith

At 12:15 PM 1/21/02 +0500, you wrote:

Dear Keith,

As I realized, our team must receive from INTAS the final sum of 737 EURO. I can get these money via Ekaterinburg Branch of VNESH TORGBANK, as we did earlier. I am sending to you "Payment request" for this sum, and you, as the coordinator, must sign it and send to Brussels. In that case I can receive money in Ekaterinburg.

Last two months I was very busy writing many reports for our activity in 2001. From that days I will begin to work with material obtained from the Polar Urals, mainly cartographic and photographic ones. WE intent to take part at PAGES meeting which will be in May in Moscow.

I wish you, your family and colleagues the best in New Year.

Best Regards,

Stepan stepan@ipae.uran.ru

Subject: Re: SCIENCE review

Dear Jesse

I am sorry for messing you about with this but I really am leading a complicated life at the moment. I am attaching my comments on The Esper et al manuscript . You will see that I think the work is genuinely interesting and potentially of wide significance. The bottom line is that you should publish this but the way the authors have chosen to present their results smacks of a lack of clarity of thought (and a lot of fudging!) . I believe that they are more concerned with trying to temper their ideas so as not to "offend" Mann et al. They choose to present their work as a generalised demonstration of how to process a tree-ring data set merely to argue against an unjustified remark made by Broecker about tree-ring reconstructions in general. This simply devalues the significance of their work as this refutation is out there in the literature already if only Broecker bothered to check. By trying to skate around the real questions that Broecker was implying - i.e. is the methodology removing the true low-frequency variance in the Mann et al curve and is the magnitude of the Medieval warmth understated ? - Esper et al are obscuring the real message of their results - namely that Mann et al do most likely lose the low frequency variance in their reconstruction and they may very well be underestimating the Medieval warmth . To get at this the authors need to be honest about what their data represent (probably summer and certainly not hemispheric wide coverage) and is this really that different from what Mann et al actually represent (even though they believe their's is a mean annual Hemispheric record). I think the authors present a too-simplistic discussion of their curve and then gloss over these difficult but important issues.

So I really think they should be published , but they should think again about the interpretation and message .

I cut Hammer ref

I just thanked "ll those who provided data"

I was looking at Graybill & Shiyatov Fig 20.6, but you are right that the warmest period was after 1160....though some argue the MWP extends into the 14th century....certainly it shows a cold 11th century. So I'll cut that reference, as requested...

I leave it to you to contact Dave Fisher as I don't know what he sent you...so get back to me asap

To: drdendro@ldeo.columbia.edu

Subject: Esper et al paper

Date: Thu, 21 Mar 2002 16:39:06 -0500

Cc: k.briffa@uea.ac.uk, p.jones@uea.ac.uk, Tom Crowley <tcrowley@duke.edu>, t.osborn@uea.ac.uk, rbradley@geo.umass.edu, Malcolm Hughes <mhughes@ltrr.arizona.edu>

Dear Ed,

I'm really sorry I couldn't be more supportive of the final version of the manuscript. I fully expected to be able to be more positive in my assessment. I was frankly very disappointed when I saw the final version--it is overwhelmingly different from the version you shared with us originally. Sadly, it seems to have suffered, and not benefited, from the review process--a very odd scenario. I fault the reviewers as much (in fact more) than I fault you for this. There are some really basic problems that they didn't seem to catch. I hope neither you nor your co-authors take this personally.

I'm trying to be as diplomatic as I can be in my discussions w/ reporters, etc. but I really wish you hadn't sprung this on us w/ no warning of the dramatic changes that were made. I'm forced to be somewhat critical, because the flaws in some of your conclusions need to be pointed out, or they will be exploited by those w/ ulterior motives. You certainly must have foreseen this, as must have the reviewers. I'm very disappointed, very disappointed indeed.

I'm sharing my comments w/ Keith, Phil, Tim, Tom, Ray, and Malcolm. I am resisting the temptation to write a letter of response to Science, although my better judgement dictates that I should...

Subject: Briffa & Osborn piece

Date: Fri, 22 Mar 2002 12:39:38 -0500

Keith and Tim,

Sadly, your piece on the Esper et al paper is more flawed than even the paper itself.

Ed, the AP release that appeared in the papers was even worse. Apparently you allowed yourself to be quoted saying things that are inconsistent with what you told me you had said.

You three all should have known better. Keith and Tim: Arguing you can scale the relationship between full Northern Hemisphere and extratropical Northern Hemisphere is *much* more problematic than even any of the seasonal issues you discuss, and this isn't even touched on in your piece. The evidence of course continues to mount (e.g., Hendy et al, Science, a couple weeks ago) that the tropical SST in the past centuries varied far more less in past centuries. Hendy et al specifically point out that there is little evidence of an LIA in the tropics in the data. The internal inconsistency here is remarkably ironic. The tropics play a very important part in our reconstruction, with half of the surface temperature estimate coming from latitudes below 30N. You know this, and in my opinion you have knowingly misrepresented our work in your piece.

This will be all be straightened out in due course. In the meantime, there is a lot of damage control that needs to be done and, in my opinion, you've done a disservice to the honest discussions we had all had in the past, because you've misrepresented the evidence. Many of us are very concerned with how Science dropped the ball as far as the review process on this paper was concerned. This never should have been published in Science, for the reason's I outlined before (and have attached for those of you who haven't seen them). I have to wonder why the functioning of the review process broke down so overtly here, Mike

Hi Mike and others,

I just read the AP release. As always, there is a bit of journalistic license that was applied to interpreting what I said. The opening statement in the release is utterly the words of the reporter. Some of the quotes are probably accurate, but of course do not include qualifiers, etc. I also talked with this journo before talking with you and would phrase things a bit more carefully now after hearing your concerns. So, I am not deceiving you in what I told you over the phone. I would not express things the same way as you in any case, because I do think that we have some legitimate differences of opinion on some issues, although I think we agree much more than we disagree. Be that as it may, talking over the phone to journalists in a rapid-fire manner is not the best way to convey ideas and information and I would have re-phrased or re-expressed some of what was written if I had seen it before it was released. This was not an option provided to me.

I think that it is a bit harse to say that the paper should not have been published. While I might wish to change some wording in the paper and express things a bit differently knowing what I know now, I don't think that the paper is fatally flawed, like you do. I should also point out that I have received a number of emails from respected scientists in global change research who do not appear to share your opinion. On the other hand, I have also received a couple of emails from certified nuts, which is what you are obviously most concerned about. I am not happy with such people, but I have also been savaged by similar nuts like John Daly in the past. So, I guess I can't win.

Finally, this whole global change debate totally sucks because it is so politicized. It reminds me too much of the ugly acid rain/forest decline debate that I was caught in the middle of years ago. I am quite happy to leave global change to others in the future.

Ed

Ed:

I just waded through all the correspondence with Mike re the Science paper and Keef's commentary. I wish to disassociate myself with Mike's comments, or at least the tone of them. I do not consider myself the final arbiter of what Science should publish, nor do I consider what you did to signify the end of civilization as we know it. Life goes on--now we have another working hypothesis to examine. Great...one of these days we'll really know what happened....until then, I find all these efforts to be really interesting. That's not to say I agree with everything you said or did, but then I don't suppose you are too enamoured of what I've done in the past either. C'est la vie.

Dear Mike, (and interested colleagues)

Given the list of people to whom you have chosen to circulate your message(s), we thought we should make a short, somewhat formal, response here. I am happy to reserve my informal response until we are face to face! We did not respond earlier because we had more pressing tasks to deal with. This is not the place to go into a long or over-detailed response to all of your comments but a few brief remarks might help to clear up a couple of misconceptions.

You consider our commentary on Ed and Jan's paper

"more flawed than even the paper itself"

on the basis that scaling the relationship between full Northern Hemisphere and extratropical Northern Hemisphere is *much* more problematic than even any of the seasonal issues we discuss. In fact we did not do this. The curve labelled Mann99 in our figure was, in fact, based on the average of only the land areas, north of 20 degrees N, extracted from your spatially-resolved reconstructions. We then scaled it by calibration against the instrumental annual temperatures from the same region. This is, just as you stress in your comments on the Esper et al. paper, what should have been done. We think that this single point addresses virtually of all your concerns. We can, of course, argue about what this means for the pre-1400 part of your reconstruction, when only 1 EOF was reconstructed, but the essential message is that we did our best to exclude the tropics (and the oceans too!) from your series so that it could more readily be compared with the other records.

The fact that we have used only the extra-tropical land from your data is not clear from the text, so we can see why you may not have appreciated this, but we think you will concede that this fact negates much of what you say and that we acted "more correctly" than you realised. Blame *Science* for being so mean with their space allocation if you want! Remember that this was an unrefereed piece and we felt justified in concentrating on one issue; that of the importance of the method of scaling and its effect on apparent "absolute" reconstruction levels. In our draft, we went on to say that this was crucial for issues of simple model sensitivity studies and climate detection, citing the work of Tom Crowley and Myles Allen, but this fell foul of the editor's knife.

You also express concerns about the calibration of Esper et al. (e.g., you say "if the authors had instead used the actual (unsmoothed) instrumental record for the extratropical northern hemisphere to scale their record, their reconstruction would be much closer to MBH99").

This point is wholly consistent with our discussion in the perspective piece, and indeed we show that in absolute terms the records are closer when Esper et al. is calibrated using unsmoothed data but since the variance is also reduced, the significance of the differences may be just as high.

Finally, we have to say that we do not feel constrained in what we say to the media or write in the scientific or popular press, by what the sceptics will say or do with our results. We can only strive to do our best and address the issues honestly. Some "sceptics" have their own dishonest agenda - we have no doubt of that. If you believe that I, or Tim, have any other objective but to be open and honest about the uncertainties in the climate change debate, then I am disappointed in you also.

Best regards

Keith (and Tim)

Cc: esper@wsl.ch, k.briffa@uea.ac.uk, t.osborn@uea.ac.uk, p.jones@uea.ac.uk, tcrowley@duke.edu, rbradley@geo.umass.edu, jto@u.arizona.edu, srutherford@virginia.edu, mann@virginia.edu

Ed,

It will take some time to digest these comments, but my initial response is one of some disappointment. I will resist the temptation to make the letter to Science available to the others on this list, because of my fears of violating the embargo policy (I know examples of where doing so has led to Science retracting a piece from publication). So thanks for also resisting the temptation to do so...

But I must point out that the piece by Malcolm and me is very similar in its content to the letter of clarification that you and I originally crafted to send to Science some weeks ago, before your co-author objected to your involvement! If there is no objection on your part, I'd be happy to send that to everyone, because it is not under consideration in Science (a quite unfortunate development, as far as I'm concerned). The only real change from that version is the discussion of the use of RCS. That is in large part Malcolm's contribution, but I stand behind what Malcolm says. I think there are some real sins of omission with regard to the use of RCS too, and it would be an oversight on our part now to comment on these.

Finally, with regard to the scaling issues, let me simply attach a plot which speaks more loudly than several pages possibly could. The plot takes Esper et al (not smoothed, but the annual values) and scales it against the full Northern Hemisphere instrumental record 1856-1990 annual mean record, and compares against the entire 20th century instrumental record (1856-1999), as well as with MBH99 and its uncertainties.

Suppose that Esper et al is indeed representative of the full Northern Hemisphere annual mean, as MBH99 purports to be. To the extent that differences emerge between the two in assuming such a scaling, I interpret them as differences which exist due to the fact that the extratropical Northern Hemisphere series and full Northern Hemisphere series likely did not co-vary in the past the same way they co-vary in the 20th century (when both are driven predominantly, in a relative sense, by anthropogenic forcing, rather than natural forcing and internal variability). What the plot shows is quite remarkable. Scaled in this way, there is remarkably little difference between Esper et al and MBH99 in the first place (the two reconstructions are largely within the error estimates of MBH99!), but moreover, where they do differ, this could be explainable in terms of patterns of enhanced mid-latitude continental response that were discussed, for example, in Shindell et al (2001) in Science last December. So I think this plot says a lot. Its say that there are some statistically significant differences, but certainly no grounds to use Esper et al to contradict MBH99 or IPCC '2001 as, sadly, I believe at least one of the published pieces tacitly appears to want to do.

It is shame that such a plot, which I think is a far more meaningful comparison of the two records, was not shown in either Esper et al or the Briffa & Osborn commentary. I've always given the group of you adequate opportunity for commentary on anything we're about to publish in Nature or Science. I am saddened that many of my colleagues (and, I have always liked to think friends) didn't afford me the same opportunity before this all erupted in our face. It could have been easily avoided. But that's water under the bridge.

Finally, before any more back-and-forths on this, I want to make sure that everyone involved understands that none of this was in any way ever meant to be personal, at least

not on my part (and if it ever has, at least on my part, seemed that way, than I offer my apologies--it was never intended that way). This is completely about the "science". To the extent that I (and/or others) feel that the science has been mis-represented in places, however, I personally will work very hard to make sure that a more balanced view is available to the community. Especially because the implications are so great in this case. This is what I sought to do w/ the NYT piece and my NPR interview, and that is what I've sought to do (and Malcolm to, as far as I'm concerned) with the letter to Science. Being a bit sloppy w/ wording, and omission, etc. is something we're all guilty of at times. But I do consider it somewhat unforgivable when it is obvious how that sloppiness can be exploited. And you all know exactly what I'm talking about!

So, in short, I think are some fundamental issues over which we're in disagreement, and where those exist, I will not shy away from pointing them out. But I hope that is not mis-interpreted as in any way personal.

I hope that suffices,

Mike

p.s. It seemed like an omission to not cc in Peck and Scott Rutherford on this exchange, so I've done that. I hope nobody minds this addition...

At 10:57 AM 4/11/02 -0400, Edward Cook wrote:

Hi Mike and Malcolm,

I have received the letter that you sent to Science and will respond to it here first in some detail and later in edited and condensed form in Science. Since much of what you comment and criticize on has been disseminated to a number of people in your (Mike's) somewhat inflammatory earlier emails, I am also sending this lengthy reply out to everyone on that same email list, save those at Science. I hadn't responded in detail before, but do so now because your criticisms will soon be in the public domain.

However, I am not attaching your letter to Science to this email since that is not yet in the public domain. It is up to you to send out your submitted letter to everyone if you wish.

I must say at the beginning that some parts of your letter to Science are as "flawed" as your claims about Esper et al. (hereafter ECS). The Briffa/Osborn perspectives piece points out an important scaling issue that indeed needs further examination. However, to claim as you do that they show that the ECS 40-year low-pass temperature reconstruction is "flawed" begs the question: "flawed" by how much? It is not at all clear that scaling the annually resolved RCS chronology to annually resolved instrumental temperatures first before smoothing is the correct way to do it. The ECS series was never created to examine annual, or even decadal, time-scale temperature variability. Rather, as was clearly indicated in the paper, it was created to show how one can preserve multi-centennial climate variability in certain long tree-ring records, as a refutation of Broecker's truly "flawed" essay. As ECS showed in their paper (Table 1), the high-frequency correlations with NH mean annual temperatures after 20-year high-pass filtering is only 0.15. That result was expected and it makes no meaningful difference if one uses only extra-tropical NH temperature data. So, while the amplitude of the temperature-scaled 40-year low-pass ECS series might be on the high end (but still plausible given the gridded borehole temperature record shown in Briffa/Osborn), scaling on the annually resolved data first would probably have the opposite effect of excessively reducing the amplitude. I am willing to accept an intermediate value, but probably not low enough to satisfy you. Really, the more important result from ECS is the enhanced pattern of multi-centennial variability in the NH extra-tropics over the past 1100 years. We can argue about the amplitude later, but the enhanced

multi-centennial variability can not be easily dismissed. I should also point out, again, that you saw Fig. 3 in ECS BEFORE it was even submitted to Science and never pointed out the putative scaling "flaw" to me at that time.

With regards to the issue of the late 20th century warming, the fact that I did not include some reference to or plot of the up-to-date instrumental temperature data (cf. Briffa/Osborn) is what I regard as a "sin of omission". What I said was that the estimated temperatures during the MWP in ECS "approached" those in the 20th century portion of that record up to 1990. I don't consider the use of "approached" as an egregious overstatement. But I do agree with you that I should have been a bit more careful in my wording there. As you know, I have publicly stated that I never intended to imply that the MWP was as warm as the late 20th century (e.g., my New York Times interview). However, it is a bit of overkill to state twice in the closing sentences of the first two paragraphs of your letter that the ECS results do not refute the unprecedented late 20th century warming. I would suggest that once is enough. ECS were also very clear about the extra-tropical nature of their data. So, what you say in your letter about the reduced amplitude in your series coming from the tropics, while perhaps worth pointing out again, is beating a dead horse. However, I must say that the "sin of omission" in the Briffa/Osborn piece concerning the series shown in their plot is a bit worrying. As they say in the data file of series used in their plot (and in Keith's April 5 email response to you), Briffa/Osborn only used your land temperature estimates north of 20 degrees and recalibrated the mean of those estimates to the same domain of land-only instrumental temperatures using the same calibration period for all of the other non-borehole series in the same way. I would have preferred it if they had used your data north of 30N to make the comparisons a bit more one-to-one. However, I still think that their results are interesting. In particular, they reproduce much of the reduced multi-centennial temperature variability seen in your complete NH reconstruction. So, if the amplitude of scaled ECS multi-centennial variability is far too high (as you would apparently suggest), it appears that it is also too low in your estimates for the NH extra-tropics north of 20N. I think that we have to stop being so aggressive in defending our series and try to understand the strengths and weaknesses of each in order to improve them. That is the way that science is supposed to work.

I must admit to being really irritated over the criticism of the ECS tree-ring data standardized using the RCS method. First of all, ECS acknowledged up front the declining available data prior to 1200 and its possible effect on interpreting an MWP in the mean record. ECS also showed bootstrap confidence intervals for the mean of the RCS chronologies and showed where the chronologies drop out. Even allowing for the reduction in the number of represented sites before 1400 (ECS Fig. 2d), and the reduction in overall sample size (ECS Fig. 2b), there is still some evidence for significantly above average growth during two intervals that can be plausibly assigned to the MWP. Of course we would like to have had all 14 series cover the past 1000-1200 years. This doesn't mean that we can't usefully examine the data in the more weakly replicated intervals. In any case, the replication in the MWP of the ECS chronology is at least as good as in other published tree-ring estimates of large-scale temperatures (e.g., NH extra-tropical) covering the past 1000+ years. It also includes more long tree-ring records from the NH temperate latitudes than ever before. So to state that "this is a perilous basis for an estimate of temperature on such a large geographic scale" is disingenuous, especially when it is unclear how many millennia-long series are contributing the majority of the temperature information in the Mann/Bradley/Hughes (MBH) reconstruction prior to AD 1400. Let's be balanced here.

I basically agree with the closing paragraph of your letter. The ECS record was NEVER intended to refute MBH. It was intended, first and foremost, to refute Broecker's essay in Science that unfairly attacked tree rings. To this extent, ECS succeeded very well. The comparison of ECS with MBH was a logical thing to do given that it has been accepted by the IPCC as the benchmark reconstruction of NH annual temperature variability and change over the past millennium. Several other papers have made similar comparisons between MBH and other even more geographically restricted estimates of past temperature. So, I don't apologize in the slightest for doing so in ECS. The correlations in Table 2 between ECS and MBH were primarily intended to demonstrate the probable large-scale, low-frequency temperature signal in ECS independent of explicitly calibrating the individual RCS chronologies before aggregating them. The results should actually have pleased you because, for the 20-200 year band, ECS and MBH have correlations of 0.60 to 0.68, depending on the period used. Given that ECS is based on a great deal of new data not used in MBH, this result validates to a reasonable degree the temperature signal in MBH in the 20-200 year band over the past 1000 years. Given the incendiary and sometimes quite rude emails that came out at the time when ECS and Briffa/Osborn were published, I could also go into the whole complaint about how the review process at Science was "flawed". I will only say that this is a very dangerous game to get into and complaints of this kind can easily cut both ways. I will submit an appropriately edited and condensed version of this reply to Science.

Regards,
Ed

<x-flowed>

Dear friends,

I am concerned about the the stressed tone of some of the words being circulated lately. Such difficulties not only hamper collegiality (which I value greatly) but also the actual progress in our field.

I think you are all fine fellows and very good scientists and that it is time to smoke the peace pipe on all this and put a temporary moratorium on more email messages until tempers cool down a bit. After this maybe we can discuss things somewhere where each party comes to the meeting beforehand with a commitment to even-handed discussion and give and take.

I hope I have not offended anyone in this message -- it is of course a personal opinion. Maybe it is an illusion or prejudice on my part, but somehow I am not convinced that the "truth" is always worth reaching if it is at the cost of damaged personal relationships....

Best wishes, Tom

Whoaah...Please don't put words in my mouth Keith, especially such inflammatory word! I was not attributing the entirety of "spin" here (which is of a pretty massive scale) to you! And I said I think such "spin", where it has occurred, is EITHER sloppy OR disingenuous. You chose to assume I was talking about you in specific, and that I was attributing the latter rather than the former. My actual words don't bear this out. In the case of the Briffa & Osborn piece, I actually tend to believe that sloppiness was the main problem. In other cases of "spin" (e.g., the skeptics web pages of Daly and his ilk) it is most clearly disingenous...I don't equate you with Daly and those folks by any stretch of the imagination. Hopefully, you know that I respect you quite a bit as a scientist! But in this case, I think you were sloppy. And the sloppiness had a real cost... And as to whether or not your statements about IPCC are fair (I didn't use the word "disservice"!), I'll leave that to each to decide. But personally, I think they were unfair, because they opened up IPCC to criticism that is not merited by what is actually said or shown in the IPCC report. Other IPCC authors who have contacted me feel the same way, and perhaps there may be an official response on the part of IPCC authors. I don't know.

But I agree that any further discussion ought to take place in the peer-reviewed literature,

Mike

At 05:09 PM 4/12/02 +0100, Keith Briffa wrote:

I agree with the sentiments expressed by Tom . However, in his latest message Mike clearly says that our perspectives piece did the IPCC a disservice. He then accuses us of spinning the ECS paper to say that MBH is an underestimate of what it purports to be and that we have been sloppy and disingenuous. Frankly this is too much to take . I am not going to let this ruin my weekend so I wait until I have calmed down and find time next week to write a response. In the meantime I just wanted to note that I disagree with these comments. Perhaps the best place to continue this discussion is in the peer review literature.

Keith

At 11:11 AM 4/12/02 -0400, Michael E. Mann wrote:

Ed and others,

I thought I too should chime in here one last time...

I'll leave it to you, Malcolm, Keith and others to debate out the issue of any additional uncertainties, biases, etc. that might arise from RCS in the presence of limited samples. That is beyond my range of expertise. But since this is a new and relatively untested approach, and it is on the basis of this approach that other estimates are being argued to be "underestimates", we would indeed have been remiss now to point this out in our letter.

The wording "perilous" perhaps should be changed, by I very much stand by the overall sentiment expressed by Malcolm in our piece with regard to RCS.

One very important additional point that Malcolm makes in his message is that conservative estimates of uncertainties, appropriate additional caveats, etc. were indeed all provided in MBH99, and I have always been careful to interpret our results in the context of these uncertainties and caveats. IPCC '2001 was careful to do so to, and based its conclusions within the context of the uncertainties (hence the choice of the conservative term "likely" in describing the apparently unprecedented nature of late 20th century warmth) and, moreover, on the collective results of many independent reconstructions. Briffa & Osborn would have you believe that IPCC '2001's conclusions in this regard rested on MBH99 alone. Frankly, Keith and Tim, I believe that is unfair to the IPCC, whether or not one cares about being fair to MBH or not.

What is unfortunate here then is that Esper et al has been "spun" i to argue that MBH99 underestimates the quantity it purports to estimate, full Northern Hemisphere annual mean temperature. Given the readily acknowledged level of uncertainty in both estimates, combined with the "apples and oranges" nature of the comparison between the two (which

I have sought to clarify in my letter to Science, and in my messages to you all, and the comparison plot I provided). I believe it is either sloppy or disingenuous reasoning to argue that this is the case. The fact that this sloppiness also readily serves the interests of the skeptics is quite unfortunate, but it is indeed beside the point!

It would probably also be helpful for me to point out, without naming names, that many of our most prominent colleagues in the climate research community, as well government funding agency representatives, have personally contacted me over the past few weeks to express their dismay at the way they believe this study was spun. I won't get into the blame game, because there's more than enough of that to go around. But when the leaders of our scientific research community and our funding managers personally alert us that they believe the credibility of our field has been damaged, I think it is time for some serious reflection on this episode.

that's my final 2 cents,
Mike

Dear Ed, Tom, Keith, etc.

In keeping w/ the spirit of Tom's and Keith's emails, I wanted to stress, before we all break for the weekend, that this is ultimately about the science, its not personal. If my comments seemed to assail e.g. Keith's motives or integrity, etc. I believe that they were misunderstood (as I tried to clarify that in my previous message), but I can see that there was a potential for misunderstanding of my message (precision in wording is very important) given the high levels of sensitivity in this debate. So I wanted to leave no uncertainty about that. And of course, I very much apologize to Keith (and Tim) if they took them my comments that way. They, again, were most decidedly not intended that way. I hope we can resolve the scientific issues objectively, and w/out injecting or any personal feelings into any of this. There are some substantial scientific differences here, lets let them play out the way they are supposed to, objectively, and in the peer reviewed literature.

Enjoy the weekend all.

cheers,

Mike

Hi Mike, Tom, etc.

Okay, I am quite happy to give this debate a rest, although I am sure that the issues brought up will still be grounds for scientific debate. I admit to getting a bit riled when I saw the ECS results on the MWP described as "perilous" because I regard that as being an unfair characterization of the work presented. Be that as it may, my reply to Science will be very carefully worded so as not to inflame the issues. Nuff said. Have a good weekend. I certainly intend to do so.

Ed

Ed and others,

I thought I too should chime in here one last time...

I'll leave it to you, Malcolm, Keith and others to debate out the issue of any additional uncertainties, biases, etc. that might arise from RCS in the presence of limited samples. serious reflection on this episode.

that's my final 2 cents,

Mike

At 10:21 AM 4/12/02 -0400, Ed Cook wrote:

Just a few comments here and then I'm done.

Dear Ed and Mike and others,

All of our attempts, so far, to estimate hemisphere-scale temperatures for the period around 1000 years ago are based on far fewer data than any of us would like. None of the datasets used so far has anything like the geographical distribution that experience with recent centuries indicates we need, and no-one has yet found a convincing way of validating the lower-frequency components of them against independent data. As Ed wrote, in the tree-ring records that form the backbone of most of the published estimates, the problem of poor replication near the beginnings of records is particularly acute, and ubiquitous. I would suggest that this problem probably cuts in closer to 1600 than 1400 in the several published series. Therefore, I accept that everything we are doing is preliminary, and should be treated with considerable caution.

Therefore, I would guess that you would apply the word "perilous" to everyone's large-scale NH reconstructions covering the past 500-1000 years including those that you have been involved in. Why the sudden increase in caution now? It sounds very self-serving to me for you to call ECS "perilous" and not describe every other large-scale reconstruction in that way as well.

I differ from Ed, and his co-authors,

in believing that these problems have a special significance for the particular implementation of RCS they used, in the light of one of their conclusions that depends heavily on that implementation.

As I understand what Ed, Keith and Hal Fritts have written at various times about RCS, and from my own limited experience with the method, it is extremely important to have strong replication, and I don't see 50-70 samples probably from 25-35 trees as a big sample. For reference, most chronologies used in dendroclimatology are based on 10-40 trees, that is 20-80 samples at 2 cores per tree for a single "site", usually a few hectares.

Here are two passages from Briffa et al., 1992: page 114, column 1, last paragraph, "For a chronology composed of the same number of samples, one would therefore expect a larger statistical uncertainty using this approach than in a chronology produced using standardization curves fitted to the data from individual trees.....The RCS method therefore requires greater chronology depth (i.e. greater sample replication) to provide the same level of confidence in its representation of the hypothetical "true" chronology." ECS mention this issue.

As I said in my previous email, we hid nothing in terms of the uncertainty concerning the pre-1200 interval. Are you suggesting that we should not have even shown those results? If so, that is ridiculous.

page 114, column 1, third paragraph, there is a discussion of the problems arising from applying RCS when pith age is not known, "In the ring-width data, the final standardization curve probably slightly underestimates the width of young trees and could therefore impart a small positive bias to the standardized ring-width indices for young rings in a number of series. However, this effect will be insignificant when the biased indices are realigned according to calendar growth years and

averaged with many other series." The problem here is that this latter condition is not met (in my view), and the "small positive bias" that may be retained could turn out to be important to the most controversial conclusion of ECS (the Medieval question).

I can't speak for Jan here, but most of the data he used came from Schweingruber's lab. I believe that pains were taken to estimate the pith offset and that Jan used this information in his RCS analyses. Jan would be best to comment here. In any case, Jan has done a number of experiments in which he has artificially added large pith offset errors into the RCS analysis and the resulting bias is small. So, I do not believe that your "view" is correct.

I also suspect that Keith and colleagues underestimated both the size and variability of the loss of years at the beginning of records, but the point stands even if this is not so. So far as I can see, ECS do not mention this issue, at least in the context of a possible positive bias.

Are you claiming that the only possible bias is positive? I can show you examples of a probable negative bias using RCS.

The discussion of RCS in the supplementary materials seems to assume good replication.

It was a generic description of the method. The replication is clearly shown in the supplementary materials section as well as in the main paper. If you don't like the replication, that is your opinion. I would love to have more replication as well. Who wouldn't. But we did show the uncertainties, which you seem to ignore in your criticism. Ironically, the ECS estimates of warmth in the MWP are not that dissimilar to those seen in MBH, as ECS Fig. 3 shows. Are the MBH estimates of MWP warmth also similarly biased?

ECS, as Ed rightly points out, clearly indicate, in both words and diagrams at several points in their paper and in the supplementary materials, that the number of sites and number of samples they used decreases sharply before 1200. Even so, ECS gives prominence (second sentence of the abstract, for example) to the reconstruction in that very period, and makes a comparison with the magnitude of 20th-century warming. All the methods, and their realizations so far, have significant problems. In our letter (Mike and I) we draw attention to a specific problem with this implementation of RCS that has a special bearing on the reconstruction of a period to which ECS have drawn attention. Hence the strong note of caution about the ECS conclusion on the comparison between the 10th/11th and late 20th centuries.

I hope it's clear from this that I don't disagree with the general proposition that all existing reconstructions of hemisphere-scale temperatures 1000 years ago (or even for all the first half of the second millennium AD) should be viewed as very preliminary. If anyone is interested I attach a short note on the replication in the year AD 1000 of records used in MBH99 to give an idea of what we are up against.

There is obviously a lot more we can debate about here. I will simply stop here by saying that I stand by the results shown in ECS and will say so in my reply to your letter, pointing out that the use of the word "perilous" could be just as easily be applied to MBH.

We all have a lot to do. I see four important tasks - 1) more investigation of the strengths and limitations of methods like RCS and age-banding - for example, how many samples would have been enough in this case, does the RC change through time? and so on; 2) use of tree-ring records where the loss of low-frequency information

is least - those with long segments from open stands; 3) the search for tree-ring parameters without age/size related trend; 4) the development of completely independent proxies with intrinsically better low-frequency fidelity.

Cheers, Malcolm

The Briffa et al reference is to the 1992 paper, Climate Dynamics, 7:111-119

Hi Ed,

OK--thanks for your response. I'll let Malcolm respond to the technical issues regarding RC. I'm not really qualified to do so myself anyway. Your other points are well taken...

Cheers,

Mike

At 12:09 PM 4/11/02 -0400, Edward Cook wrote:

Hi Mike,

Thanks for the reply. I too do not want to see anything personal in our disagreements. It would be a shame if it got to that and it shouldn't. I don't think that the science we are talking about is sufficiently known yet to claim the "truth", which is why we are having some of our disagreements. I mainly wanted to clarify some issues relating to some criticisms of the ECS results that I thought were not totally fair. My biggest complaint is with Malcolm's contribution to your letter because it really isn't fair to use such words as "perilous". ECS did not hide anything and the uncertainties are clearly indicated in EGS

> Figs. 2 and 3. So, you can make your own judgement. However,

Malcolm's opinion does not invalidate the ECS record. If Malcolm's statement is correct, then ALL previous estimates of NH temperature over the past 1000 years are "perilous", especially before AD 1400 when the number of series available declines significantly in most records.

Ed

Ed,

It will take some time to digest these comments, but my initial response is one of some disappointment. I will resist the temptation to make the letter to Science available to the others on this list, because of my fears of violating the embargo policy (I know examples of where doing so has led to Science retracting a piece form publication). So thanks for also resisting the temptation to do so...

But I must point out that the piece by Malcolm and me is very similar in its content to the letter of clarification that you and I originally crafted to send to Science some weeks ago, before your co-author objected to your involvement! If there is no objection on your part, I'd be happy to send that to everyone, because it is not under consideration in Science (a quite unfortunate development, as far as I'm concerned). The only real change from that version is the discussion of the use of RCS. That is in large part Malcolm's contribution, but I stand behind what

> Malcolm says. I think there are some real sins of omission with

regard to the use of RCS too, and it would be an oversight on our part now to comment on these.

Finally, with regard to the scaling issues, let me simply attach a plot which speaks more loudly than several pages possibly could. The plot takes Esper et al (not smoothed, but the annual values) and scales it against the full Northern Hemisphere instrumental record 1856-1990 annual mean record, and compares against the entire 20th century instrumental record (1856-1999), as well as with MBH99 and its uncertainties.

Suppose that Esper et al is indeed representative of the fullNorthern Hemisphere annual mean, as MBH99 purports to be. To the extent that differences emerge

between the two in assuming such a scaling, I interpret them as differences which exist due to the fact that the extratropical Northern Hemisphere series and full Northern Hemisphere series likely did not co-vary in the past the same way they co-vary in the 20th century (when both are driven predominantly, in a relative sense, by anthropogenic forcing, rather than natural forcing and internal variability). What the plot shows is quite remarkable. Scaled in this way, there is remarkably little difference between Esper et al and MBH99 in the first place (the two reconstructions are largely within the error estimates of MBH99!), but moreover, where they do differ, this could be explainable in terms of patterns of enhanced mid-latitude continental response that were discussed, for example, in Shindell et al (2001) in Science last December. So I think this plot says a lot. Its say that there are some statistically significant differences, but certainly no grounds to use Esper et al to contradict MBH99 or IPCC '2001 as, sadly, I believe at least one of the published pieces tacitly appears to want to do.

It is shame that such a plot, which I think is a far more meaningful comparison of the two records, was not shown in either Esper et al or the Briffa & Osborn commentary. I've always given the group of you adequate opportunity for commentary on anything we're about to publish in Nature or Science. I am saddened that many of my colleagues (and, I have always liked to think friends) didn't affort me the same opportunity before this all erupted in our face. It could have been easily avoided. But that's water under the bridge.

>

Finally, before any more back-and-forths on this, I want to make sure that everyone involved understands that none of this was in any way ever meant to be personal, at least not on my part (and if it ever has, at least on my part, seemed that way, than I offer my apologies--it was never intended that way). This is completely about the "science". To the extent that I (and/or others) feel that the science has been mis-represented in places, however, I personally will work very hard to make sure that a more balanced view is available to the community. Especially because the implications are so great in this case. This is what I sought to do w/ the NYT piece and my NPR interview, and that is what I've sought to do (and Malcolm to, as far as I'm concerned) with the letter to Science. Being a bit sloppy w/ wording, and omission, etc. is something we're all guilty of at times. But I do consider it somewhat unforgivable when it is obvious how that sloppiness can be exploited. And you all know exactly what I'm talking about! So, in short, I think are some fundamental issues over which we're in disagreement, and where those exist, I will not shy away from pointing them out. But I hope that is not mis-interpreted as in any way personal. I hope that suffices,

>

Mike

p.s. It seemed like an omission to not cc in Peck and Scott Rutherford on this exchange, so I've done that. I hope nobody minds this addition...

At 10:57 AM 4/11/02 -0400, Edward Cook wrote:

Hi Mike and Malcolm,

I have received the letter that you sent to Science and will respond to it here first in some detail and later in edited and condensed form in Science.

Since much of what you comment and criticize on

has been disseminated to a number of people in your (Mike's) somewhat inflammatory earlier emails, I am also sending this lengthy reply out to everyone on that same email list, save those at Science. I hadn't responded in detail before, but do so now because your criticisms will soon be in the public domain. However, I am not attaching your letter to Science to this email since that is not yet in the public domain. It is up to you to send out your submitted letter to everyone if you wish.

I must say at the beginning that some parts of your letter to Science are as "flawed" as your claims about Esper et al. (hereafter ECS). The Briffa/Osborn perspectives piece points out an important scaling issue that indeed needs further examination. However, to claim as you do that they show that the ECS 40-year low-pass temperature reconstruction is "flawed" begs the question: "flawed" by how much? It is not at all clear that scaling the annually resolved RCS chronology to annually resolved instrumental temperatures first before smoothing is the correct way to do it. The ECS series was never created to examine annual, or even decadal, time-scale temperature variability. Rather, as was clearly indicated in the paper, it was created to show how one can preserve multi-centennial climate variability in certain long tree-ring records, as a refutation of Broecker's truly "flawed" essay. As ECS showed in their paper (Table 1), the high-frequency correlations with NH mean annual temperatures after 20-year high-pass filtering is only 0.15. That result was expected and it makes no meaningful difference if one uses only extra-tropical NH temperature data. So, while the amplitude of the temperature-scaled 40-year low-pass ECS series might be on the high end (but still plausible given the gridded borehole temperature record shown in Briffa/Osborn), scaling on the annually resolved data first would probably have the opposite effect of excessively

> reducing the amplitude. I am willing to accept an

intermediate value, but probably not low enough to satisfy you. Really, the more important result from ECS is the enhanced pattern of multi-centennial variability in the NH extra-tropics over the past 1100 years. We can argue about the amplitude later, but the enhanced multi-centennial variability can not be easily dismissed. I should also point out, again, that you saw Fig. 3 in ECS BEFORE it was even submitted to Science and never pointed out the putative scaling "flaw" to me at that time.

With regards to the issue of the late 20th century warming, the fact that I did not include some reference to or plot of the up-to-date instrumental temperature data (cf. Briffa/Osborn) is what I regard as a "sin of omission". What I said was that the estimated temperatures during the MWP in ECS "approached" those in the 20th century portion of that record up to 1990. I don't consider the use of "approached" as an egregious overstatement. But I do agree with you that I should have been a bit more careful in my wording there. As you know, I have publicly stated that I never intended to imply that the

MWP was as warm as the late 20th century (e.g.,

> my New York Times interview). However, it is a

bit of overkill to state twice in the closing sentences of the first two paragraphs of your letter that the ECS results do not refute the unprecedented late 20th century warming. I would suggest that once is enough.

ECS were also very clear about the extra-tropical nature of their data. So, what you say in your letter about the reduced amplitude in your series coming from the tropics, while perhaps worth pointing out again, is beating a dead horse.

However, I must say that the "sin of omission" in the Briffa/Osborn piece concerning the series shown in their plot is a bit worrying. As they say in the data file of series used in their plot (and in Keith's April 5 email response to you),

Briffa/Osborn only used your land temperature estimates north of 20 degrees and recalibrated the mean of those estimates to the same domain of land-only instrumental temperatures using the same calibration period for all of the other non-borehole series in the same way. I would have preferred it if they had used your data north of 30N to make the comparisons a bit more one-to-one. However, I still think that their results are interesting. In particular, they reproduce much of the reduced multi-centennial temperature

variability seen in your complete NH reconstruction. So, if the amplitude of scaled ECS multi-centennial variability is far too high (as you would apparently suggest), it appears that it is also too low in your estimates for the NH extra-tropics north of 20N. I think that we have to stop being so aggressive in defending our series and try to understand the strengths and weaknesses of each in order to improve them.

That is the way that science is supposed to work. I must admit to being really irritated over the criticism of the ECS tree-ring data standardized using the RCS method. First of all, ECS

acknowledged up front the declining available data prior to 1200 and its possible effect on interpreting an MWP in the mean record. ECS also showed bootstrap confidence intervals for the mean of the RCS chronologies and showed where the chronologies drop out. Even allowing for the reduction in the number of represented sites before 1400 (ECS Fig. 2d), and the reduction in overall sample size (ECS Fig. 2b), there is still some evidence for significantly above average growth during two intervals that can be plausibly assigned to the MWP. Of course

> we would like to have had all 14 series cover the

past 1000-1200 years. This doesn't mean that we can't usefully examine the data in the more weakly replicated intervals. In any case, the replication in the MWP of the ECS chronology is at least as good as in other published tree-ring estimates of large-scale temperatures (e.g., NH extra-tropical) covering the past 1000+ years. It also includes more long tree-ring records from the NH temperate latitudes than ever before. So to state that "this is a perilous basis for an estimate of temperature on such a large geographic scale"

is disingenuous, especially when it is unclear how many millennia-long series are contributing the majority of the temperature information in the Mann/Bradley/Hughes (MBH) reconstruction prior to AD 1400. Let's be balanced here. I basically agree with the closing paragraph of your letter. The ECS record was NEVER intended to refute MBH. It was intended, first and foremost, to refute Broecker's essay in Science that unfairly attacked tree rings. To this extent, ECS succeeded very well. The comparison of ECS with MBH was a logical thing to do given that it has been accepted by the

> IPCC as the benchmark reconstruction of NH

annual temperature variability and change over the past millennium. Several other papers have made similar comparisons between MBH and other even more geographically restricted estimates of past temperature. So, I don't apologize in the slightest for doing so in ECS. The correlations in Table 2 between ECS and MBH were primarily intended to demonstrate the probable large-scale, low-frequency temperature signal in ECS independent of explicitly calibrating the individual RCS chronologies before aggregating them. The results should actually have pleased you because, for the 20-200 year band, ECS and MBH have correlations of 0.60 to 0.68, depending on the period used. Given that ECS is based on a great deal of new data not used in MBH, this result validates to a reasonable degree the temperature signal in MBH in the 20-200 year band over the past 1000 years. Given the incendiary and sometimes quite rude emails that came out at the time when ECS and Briffa/Osborn were published, I could also go into the whole complaint about how the review process at Science was "flawed". I will only say that this is a very dangerous game to get into and complaints of this kind can easily cut both ways. I will submit an appropriately edited and condensed version of this reply to Science.

Regards,

Ed

Hi Tim,

Thanks for your message. Yes, you guys have us beat on the early monday end of things!

Your points are all taken. I think we all agree there is much work left to be done, more than enough for all of us to continue to be involved in constructive collaboration, etc.

Scott and I, for example, are almost done writing up the work based on your visit w/ us last year, and will send the initial draft on to you, Keith, and the others involved in the near future. It will be a good chance to try to address a lot of these questions in an article of adequate length to discuss the nuances that unfortunately cannot be addressed in a shorter piece.

I also appreciate your more detailed comments about the comparisons, etc. Your points are all reasonable ones. We can maintain an honest difference about how well those points were conveyed in the Science piece (for example, you can imagine how the statement in your piece

"This record has a smaller amplitude of century-to-century variability, and is consistently at or near the upper limit of alternate records produced by other researchers" might indeed have been interpreted as setting MBH99 apart as, in your words, an "outlier").

We have good reason to believe that our reconstruction *will* in fact underestimate extratropical temperature means but far less so full globe/hemisphere-means prior to the 18th century because the basis functions that primarily set the extratropics apart from the full hemispheric patterns (e.g., NAO type patterns and other anomaly patterns largely carried by EOFs #2 and #3) start to drop out from our basis set prior to the 18th century, while the pattern that best resolves the full global and/or hemispheric mean (with note from MBH98, particularly large loadings primarily in the tropics and subtropics) still remains. That is why we have never published an *extratropical* temperature reconstruction prior to the 18th century. I would be happy to discuss this point with you and Keith and others in more detail. Thus, I have compared Esper et al w/ our records in the manner described in my previous email, which I think allows us to diagnose the extent to which differing high-latitude and full-hemispheric patterns may, at times, explain the somewhat modest differences between the records when similarly scaled to the full hemispheric 1856-1990 mean, and always, within the context of the diagnosed uncertainties. There is no guarantee, as you say, that the uncertainties are correct, but I personally believe they'll stand up over time. You can call me on this 10 years from now, and somebody will owe somebody a beer...

In any case, I hope and fully expect we can all continue to all be engaged in constructive interaction & hopefully continued collaboration. It will require some sensitivity on all our part to the larger issues surrounding our work, and the way it gets presented to the broader community, but I don't think that should be all that difficult.

I look forward to these more constructive interactions. I'll do my best to foster them,

Mike

Dear all,

well, the time zone may let you have the last word before the weekend, but we can get the first word in on a Monday morning!

At 22:35 12/04/02, Michael E. Mann wrote:

In keeping w/ the spirit of Tom's and Keith's emails, I wanted to stress, before we all break for the weekend, that this is ultimately about the science, its not personal. If my comments seemed to assail e.g. Keith's motives or integrity, etc. I believe that they were misunderstood (as I tried to clarify that in my previous message), but I can see that there was a potential for misunderstanding of my message (precision in wording is

very important) given the high levels of sensitivity in this debate. So I wanted to leave no uncertainty about that. And of course, I very much apologize to Keith (and Tim) if they took them my comments that way. They, again, were most decidedly not intended that way.

Thanks for clarifying that, Mike. I think that both Keith and I interpreted your earlier e-mail as being more critical of us than you actually meant it to be. Most issues surrounding the recent Esper et al. and Briffa & Osborn pieces seem to have been covered adequately already. There are just a couple of issues on which I'd like to add a few comments, hopefully clarifying the situation rather than opening up more avenues for debate.

The first relates to the purpose and style of the Briffa & Osborn piece. Perspectives are brief, non-technical and not peer-reviewed. Our instructions were: "The Perspective should provide an overview of recent research in the field and explain to the general reader why the work is particularly exciting." Is it any surprise then that we should focus on the new insights provided by the Esper et al. work, and that it suggests a different climate history than earlier work? And that the constraints of the perspectives format (in terms of length, audience and style) prevented us from listing ALL the caveats and uncertainties related to this and earlier reconstructions and that might be of relevance to their intercomparison? I don't think it is surprising, nor do I think we should be criticised for it.

Moreover, despite the constraints of the perspectives format, I think we were very careful with our wording to avoid misleading the reader. The reference to the IPCC, for example, was not at all sloppy - the opposite, in fact, since it was very carefully worded: the IPCC Synthesis Report is referred to, rather than the full TAR, and it is quite true that there is a focus on the reconstruction of Mann et al. in the former. As Mike says, IPCC conclusions were based on other work too. But I'd guess that many of the readers of our perspective won't have read the full IPCC report, so we thought it valid to focus on the difference between the new work and that shown in the Synthesis Report (which more will have seen). To do this is certainly not unfair to the IPCC. It would only have been unfair if we had implied that the IPCC had ignored this new work - but of course we weren't doing that, because how could one expect the TAR to consider work that is published a year after the TAR itself? We were similarly careful with our wording in our brief mention of the MWP, by saying it is "more pronounced" in Esper et al. - this doesn't mean it is warmer than the others (and thus has no implications for the IPCC conclusion of recent unusual warmth), rather it is pronounced because it is followed by stronger cooling.

The second issue is our re-calibration of the reconstructions. While it hasn't been explicitly stated, I get the impression that this is considered by some to be a poor thing to do. The particular re-calibration we do has a number of effects, including making the Mann et al. reconstruction appear more consistently at the top of the range of alternatives. But please let me assure you (Mike, Ray and Malcolm) that the reason for re-calibrating the records is definitely *not* to make your record appear as an outlier, and I hope you believe me. Indeed, in Jones, Osborn & Briffa (2001: Science 292, 662-667) we showed various NH records *without* applying our re-calibration. We produced our first comparison of records for an earlier Science perspectives piece in 1999 (Briffa & Osborn, 1999) and thought it would be useful to do a re-calibration to remove some of the reasons for inter-reconstruction differences (which can be due to: different proxy data, different statistical methods, different calibration target and different calibration period). The latter two reasons were removed by re-calibrating against a common target series and over a common period. We updated this in Briffa et al. (2001) and acknowledged that the target series (in terms of its spatial and seasonal definition) may not be optimal in all cases. Indeed, it may be especially sub-optimal for Mann et al., because their reconstruction approach combines the proxy records to optimally reconstruct full NH, annual mean T (whereas we have selected land north of 20N, warm-season T as our target for the recalibration). Despite this, we felt justified in doing the recalibration because the Mann et al. series still outperformed

the others in terms of its correlation with the instrumental record over the calibration period! In our latest piece, we have updated the intercomparison in two ways (as well as including new series): (i) we took the spatially-resolved gridded reconstructions of Mann et al. and extracted only land boxes north of 20N; and (ii) we used annual, not warm-season, temperature as the target. The first of these (as explained by Keith and I in an earlier e-mail, which is repeated below because it didn't get sent to all of you first time round) deals with all the points raised by Mike about tropical versus extratropical differences. I would again argue that we were not sloppy, because these changes to our intercomparison were carefully thought out.

So that explains what we have done and why. There is some sensitivity, clearly, to calibration choices, which implies to me that the true uncertainty ranges are probably larger than those estimated solely from the statistical properties of calibration residuals (as used by Briffa et al., and [I think] by Mann et al.). There is clearly more progress to be made!

Best regards to you all

Tim

Dear Mike, (and interested colleagues)

Given the list of people to whom you have chosen to circulate your message(s), we thought we should make a short, somewhat formal, response here. I am happy to reserve my informal response until we are face to face! We did not respond earlier because we had more pressing tasks to deal with. This is not the place to go into a long or over-detailed response to all of your comments but a few brief remarks might help to clear up a couple of misconceptions.

You consider our commentary on Ed and Jan's paper

"more flawed than even the paper itself"

on the basis that scaling the relationship between full Northern Hemisphere and extratropical Northern Hemisphere is *much* more problematic than even any of the seasonal issues we discuss. In fact we did not do this. The curve labelled Mann99 in our figure was, in fact, based on the average of only the land areas, north of 20 degrees N, extracted from your spatially-resolved reconstructions. We then scaled it by calibration against the instrumental annual temperatures from the same region. This is, just as you stress in your comments on the Esper et al. paper, what should have been done. We think that this single point addresses virtually of all your concerns. We can, of course, argue about what this means for the pre-1400 part of your reconstruction, when only 1 EOF was reconstructed, but the essential message is that we did our best to exclude the tropics (and the oceans too!) from your series so that it could more readily be compared with the other records.

The fact that we have used only the extra-tropical land from your data is not clear from the text, so we can see why you may not have appreciated this, but we think you will concede that this fact negates much of what you say and that we acted "more correctly" than you realised. Blame *Science* for being so mean with their space allocation if you want! Remember that this was an unrefereed piece and we felt justified in concentrating on one issue; that of the importance of the method of scaling and its effect on apparent "absolute" reconstruction levels. In our draft, we went on to say that this was crucial for issues of simple model sensitivity studies and climate detection, citing the work of Tom Crowley and Myles Allen, but this fell foul of the editor's knife.

You also express concerns about the calibration of Esper et al. (e.g., you say "if the authors had instead used the actual (unsmoothed) instrumental record for the

extratropical northern hemisphere to scale their record, their reconstruction would be much closer to MBH99").

This point is wholly consistent with our discussion in the perspective piece, and indeed we show that in absolute terms the records are closer when Esper et al. is calibrated using unsmoothed data but since the variance is also reduced, the significance of the differences may be just as high.

Finally, we have to say that we do not feel constrained in what we say to the media or write in the scientific or popular press, by what the sceptics will say or do with our results. We can only strive to do our best and address the issues honestly. Some "sceptics" have their own dishonest agenda - we have no doubt of that. If you believe that I, or Tim, have any other objective but to be open and honest about the uncertainties in the climate change debate, then I am disappointed in you also.

Best regards

Keith (and Tim)

The particular re-calibration we do has a number of effects, including making the Mann et al. reconstruction appear more consistently at the top of the range of alternatives. But please let me assure you (Mike, Ray and Malcolm) that the reason for re-calibrating the records is definitely **not** to make your record appear as an outlier, and I hope you believe me. Indeed, in Jones, Osborn & Briffa (2001: Science 292, 662-667) we showed various NH records **without** applying our re-calibration.

We produced our first comparison of records for an earlier Science perspectives piece in 1999 (Briffa & Osborn, 1999) and thought it would be useful to do a re-calibration to remove some of the reasons for inter-reconstruction differences (which can be due to: different proxy data, different statistical methods, different calibration target and different calibration period). The latter two reasons were removed by re-calibrating against a common target series and over a common period. We updated this in Briffa et al. (2001) and acknowledged that the target series (in terms of its spatial and seasonal definition) may not be optimal in all cases. Indeed, it may be especially sub-optimal for Mann et al., because their reconstruction approach combines the proxy records to optimally reconstruct full NH, annual mean T (whereas we have selected land north of 20N, warm-season T as our target for the recalibration). Despite this, we felt justified in doing the recalibration because the Mann et al. series still outperformed the others in terms of its correlation with the instrumental record over the calibration period! In our latest piece, we have updated the intercomparison in two ways (as well as including new series): (i) we took the spatially-resolved gridded reconstructions of Mann et al. and extracted only land boxes north of 20N; and (ii) we used annual, not warm-season, temperature as the target. The first of these (as explained by Keith and I in an earlier e-mail, which is repeated below because it didn't get sent to all of you first time round) deals with all the points raised by Mike about tropical versus extratropical differences. I would again argue that we were not sloppy, because these changes to our intercomparison were carefully thought out.

So that explains what we have done and why. There is some sensitivity, clearly, to calibration choices, which implies to me that the true uncertainty ranges are probably larger than those estimated solely from the statistical properties of calibration residuals (as used by Briffa et al., and [I think] by Mann et al.). There is clearly more progress to be made!

Best regards to you all

Tim

Dear Mike, (and interested colleagues)

Given the list of people to whom you have chosen to circulate your message(s), we thought we should make a short, somewhat formal, response here. I am happy to reserve my informal response until we are face to face! We did not respond earlier because we

had more pressing tasks to deal with. This is not the place to go into a long or over-detailed response to all of your comments but a few brief remarks might help to clear up a couple of misconceptions.

You consider our commentary on Ed and Jan's paper "more flawed than even the paper itself"

on the basis that scaling the relationship between full Northern Hemisphere and extratropical Northern Hemisphere is *much* more problematic than even any of the seasonal issues we discuss. In fact we did not do this. The curve labelled Mann99 in our figure was, in fact, based on the average of only the land areas, north of 20 degrees N, extracted from your spatially-resolved reconstructions. We then scaled it by calibration against the instrumental annual temperatures from the same region. This is, just as you stress in your comments on the Esper et al. paper, what should have been done. We think that this single point addresses virtually of all your concerns. We can, of course, argue about what this means for the pre-1400 part of your reconstruction, when only 1 EOF was reconstructed, but the essential message is that we did our best to exclude the tropics (and the oceans too!) from your series so that it could more readily be compared with the other records.

The fact that we have used only the extra-tropical land from your data is not clear from the text, so we can see why you may not have appreciated this, but we think you will concede that this fact negates much of what you say and that we acted "more correctly" than you realised. Blame *Science* for being so mean with their space allocation if you want! Remember that this was an unrefereed piece and we felt justified in concentrating on one issue; that of the importance of the method of scaling and its effect on apparent "absolute" reconstruction levels. In our draft, we went on to say that this was crucial for issues of simple model sensitivity studies and climate detection, citing the work of Tom Crowley and Myles Allen, but this fell foul of the editor's knife.

You also express concerns about the calibration of Esper et al. (e.g., you say "if the authors had instead used the actual (unsmoothed) instrumental record for the extratropical northern hemisphere to scale their record, their reconstruction would be much closer to MBH99").

This point is wholly consistent with our discussion in the perspective piece, and indeed we show that in absolute terms the records are closer when Esper et al. is calibrated using unsmoothed data but since the variance is also reduced, the significance of the differences may be just as high.

Finally, we have to say that we do not feel constrained in what we say to the media or write in the scientific or popular press, by what the sceptics will say or do with our results. We can only strive to do our best and address the issues honestly. Some "sceptics" have their own dishonest agenda - we have no doubt of that. If you believe that I, or Tim, have any other objective but to be open and honest about the uncertainties in the climate change debate, then I am disappointed in you also.

Best regards

Keith (and Tim)

Phil,

I can't quite see what all the fuss is about Watson - why should he be re-nominated anyway? Why should not an Indian scientist chair IPCC? One could argue the CC issue is more important for the South than for the North. Watson has perhaps thrown his weight about too much in the past. The science is well covered by Susan Solomon in WGI, so why not get an engineer/economist since many of the issues now raised by CC are more to do with energy and money, than natural science.

If the issue is that Exxon have lobbied and pressured Bush, then OK, this is regrettable but to be honest is anyone really surprised? All these decisions about IPCC chairs and co-chairs are deeply political (witness DEFRA's support of Martin Parry for getting the WGII nomination).

----- Original Message -----

Subject: SSI Alert: IPCC Chair Vote
Date: Fri, 19 Apr 2002 18:00:59 -0400
From: "SSI Mailbox" <ssi@ucsusa.org>

***** EXECUTIVE SUMMARY *****

ISSUE: Today - April 19, 2002, the Intergovernmental Panel on Climate Change (IPCC) plenary voted for Dr. Rajendra Pachauri as the sole chair of the IPCC. Dr. Pachauri, an

economist and engineer, will replace Dr. Robert Watson, an atmospheric chemist, as chair of the IPCC. This outcome was actively sought by the Bush Administration at the behest of the most conservative elements of the fossil fuel industry. This development threatens to undermine the scientific credibility and integrity of the IPCC and may weaken the job this extraordinary body has done to bring the world's attention to one of the most pressing environmental problems.

ACTION: Monitor your local paper and respond to news stories with a letter-to-the-editor.

MAIN MESSAGE: Given the Bush Administration's consistent opposition to climate change mitigation, it is especially imperative at this time that the scientific community and Dr. Pachauri work together to ensure that the IPCC remains a strong and credible scientific process.

DEADLINE: As soon as possible after the story runs in your paper -- preferably the same day but no later than a day or two after.

*** THE ISSUE ***

According to a report by Associated Press today (appended below), Dr. Rajendra Pachauri was elected as Chair of the IPCC at a plenary meeting in Geneva. As you would be aware from our earlier SSI alerts of the past several weeks, this follows on from intense lobbying of the US government by the fossil fuel industry to remove Dr. Robert Watson as Chair. Although reports from Geneva are still sketchy, our sources on the ground tell us that there was intense behind-the-scenes lobbying by Saudi Arabia, with assistance from Don Pearlman -- a well known oil and gas lobbyist with strong connections to industry-backed organizations opposed to climate change mitigation. Through their maneuvering, the co-chair compromise approach -- comprised of former chair Dr. Robert Watson and Dr. Pachauri -- was not considered. As a result of this election, there is considerable concern in the climate science and environmental communities -- reinforced by the intensive lobbying from fossil fuel interests on this decision -- that the Bush Administration's lack of support for former IPCC Chair Dr. Robert Watson signals a more general lack of support for the IPCC as a credible international scientific assessment process that provides governments with sound information on climate

science, impacts, and solutions.

By supporting Dr. Pachauri for primarily political purposes, the Bush Administration has seriously threatened the scientific credibility of the IPCC process. The conservative fossil fuel interests should be exposed for their role in influencing the US government's stance on this issue, and the IPCC process must remain a scientifically credible and non-politicized process.

The next IPCC Climate Change Assessment is due out in five years, and it is the chair's role to oversee this complex process. The scientific community's voice is important in this issue to ensure that the IPCC process remains strong under the leadership of Dr. Pachauri and that the Bush Administration does not erode the effectiveness of this important international body.

*** THE ACTION ***

-- Monitor your local paper and respond to news stories with a letter-to-the-editor.

Information on how and to whom to submit a LTE is usually found right on the Letters Page in your paper. Many papers now accept letters via email. If you can't find the information you need, simply call the paper and ask how to go about submitting a letter in response to a recently published article.

To increase the chances that your letter will be published, do the following:

- keep it under 200 words and stay focused on one or two main points you'd like to make;
- focus on a local angle, if possible, that adds something new to the story that appeared in your paper;
- be sure to include your name, address, and daytime phone number; the paper will contact you before printing your letter; and
- submit the letter on the same day the story appears, if possible.

[For additional help with writing an effective letter to the editor, you may turn to the reference guide on the SSI member page at <[1]<http://www.ucsusa.org/ssimembers/index.html> >.]

-- MAIN MESSAGE: Given the Bush Administration's consistent opposition to climate change mitigation, it is especially imperative at this time that the scientific community and Dr. Pachauri work together to ensure that the IPCC remains a strong and credible scientific process.

-- TIMING: Your letter to the editor should reach your paper within a few days of the publication of the story to increase the chances of it being published.

-- SPECIAL NOTE: If your paper did not carry the story at all yet, send an LTE describing the story and emphasizing that this issue is of great interest to the paper's subscribers.

*** SUPPORTING MESSAGES ***

-- [Be sure to include a description of your scientific expertise, your involvement with the IPCC process, or the importance of the climate issue to your community.]

-- For the past 10 years, the IPCC's science has been the foundation for sound policymaking on the climate issue. The IPCC's unique intergovernmental approach to scientific consensus has worked amazingly well but is now threatened.

-- It is disturbing that the Bush Administration sought and received advice from the fossil fuel industry on the leadership of an important scientific body such as the IPCC. A politicized IPCC threatens the integrity and credibility of the scientific process.

-- There are fears that it will now be easier for the US to distance itself from the IPCC process. You may point out that the US already rejected the Kyoto protocol last year.

-- It is vital that the scientific process for the next Assessment Report (due out in another five years) not be compromised so that the IPCC continues to produce sound science on climate change.

-- The credibility of the IPCC's Third Assessment Report (TAR) findings were strongly affirmed by the US National Academy of Sciences (NAS), which published its supportive report in response to President Bush's request for an independent assessment on the state of climate science.

*** SUPPLEMENTAL INFORMATION ***

-- Dr Rajendra K. Pachauri is an Indian engineer and economist. Pachauri, formerly one of the five vice chairs of the IPCC, is highly regarded but will be the first non-atmospheric chemist as chair of the IPCC.

-- For more information on the ExxonMobil memo urging the Bush Administration to remove Dr. Watson from his position as IPCC Chair, please see

< [2]<http://www.nrdc.org/media/docs/020403.pdf> >.

-- For information on the Saudi/Pearlman connection, see the summary by Jeremy Leggett, author of "The Carbon War", at

< [3]<http://www.carbonwar.com/ccchrono.html> >.

-- IPCC - Intergovernmental Panel on Climate Change: The Intergovernmental Panel on Climate Change (IPCC) was established in 1988 under the auspices of the United Nations Environment Programme and the World Meteorological Organization for the purpose of assessing "the scientific, technical and socioeconomic information relevant for the understanding of the risk of human-induced climate change." To date, the IPCC has issued three comprehensive assessments. The first assessment report (FAR) was released in 1990, the second assessment report (SAR) was released in 1996, and the third assessment report (TAR) was released in 2001. These assessments are based on "published and peer reviewed scientific technical literature"

U.S. scientist voted off international climate panel

By JONATHAN FOWLER, Associated Press Writer

GENEVA - A U.S. scientist was voted off an international climate panel Friday following what campaigners claimed was pressure from the oil industry and Washington.

Atmospheric scientist Robert Watson was seeking re-election as head of the Intergovernmental Panel on Climate Change. World Meteorological Organization (news - web sites) spokeswoman Mo Lagarde said Watson was defeated by Indian challenger Rajendra Pachauri. Some 76 countries supported Pachauri, while 49 voted for Watson in the secret ballot, she said.

Seven nations voted for Jose Goldemberg, a Brazilian (news - web sites) who entered the race this week.

The WMO and the U.N. Environment Program jointly host the IPCC's offices and organized the Geneva meeting.

Environmental groups have accused the administration of President George W. Bush (news - web sites) of caving in to a request from Exxon Mobil that it try to remove Watson, a leading expert on global warming (news - web sites), because he had consistently warned governments of the dangers of climate change.

"The fossil fuel industry and the U.S. government will be celebrating their success in kicking out Bob Watson, an experienced scientist who understood that urgent action is needed to tackle global climate change," said Kate Hampton, international climate co-ordinator for British-based Friends of the Earth (news - web sites). "The Bush administration and its friends would rather shoot the messenger than listen to the message," Hampton said in a statement.

The Swiss-based Worldwide Fund for Nature said it was worried by the "apparent politicization" of the IPCC.

"WWF is concerned that oil and gas interests had too much to say in the removal of Dr. Watson as chairman of what should be an impartial, scientific body," said Jennifer Morgan, Director of WWF's Climate Program.

But, Morgan said, the "IPCC is a vibrant group of scientists and WWF looks forward to working closely with Dr. Pachauri to protect the integrity of the IPCC and ensure that it continues to produce sound science on climate change."

The U.S. State Department said earlier this month that it would support Pachauri, who was the Indian government's nominee, to become the next chair.

Two weeks ago, the Natural Resources Defense Council, a Washington, D.C.-based environmental group, said the White House's Council on Environmental Quality received a memo from Exxon Mobil in February 2001 that asked, "Can Watson be replaced now at the request of the U.S.?"

The memo, which the group said it obtained through the Freedom of Information Act, also recommended that the administration "restructure the U.S. attendance at upcoming IPCC meetings to assure none of the Clinton/Gore proponents are involved in any decisional activities."

U.S. officials were unavailable for comment.

Watson has been an outspoken proponent of the idea that fossil fuel emissions contribute to rising global temperatures. He has led the panel since 1996 and is also

the chief scientist of the World Bank (news - web sites).
Pachauri is an engineer and an economist and is the director
of the Tata Energy Research Institute in New Delhi, India.

Simon,

A version of this for In Tyndall please - you should add the relevant EPSRC web site if you can track it down.

Mike

EPSRC invests in adventurous ideas

EPSRC is to establish an adventurous research fund. A total of £4.5 million has been earmarked for research projects that include a mixture of disciplines and as such may face barriers to selection under EPSRCs core research programmes. The pilot initiative will be launched with a call for outline proposals at the end of May. The closing date will be at end of July. Those successful at the outline stage will be asked to submit full proposals by December. The new funds principal novelty is an emphasis on funding people to work in other disciplines or between disciplines. EPSRC will fund any research project that falls within its centre of gravity. We are happy for it to be 49 per cent in another research council remit, so long as the majority is in the EPSRC remit, says Hylton. Equally, EPSRC has not capped how much money people can apply for. Another key difference is the way in which the proposals will be evaluated. It will be a two-stage process with outline proposals followed by full proposals. The outline stages of applying to the adventure fund are to be assessed anonymously. In addition, the initiative will have its own bespoke outline application form, proposal form and referees assessment form. EPSRC also hopes the initiative will go some way to changing UK research culture.

Hi Keith,

Of course, I agree with you. We both know the probable flaws in Mike's recon, particularly as it relates to the tropical stuff. Your response is also why I chose not to read the published version of his letter. It would be too aggravating. The only way to deal with this whole issue is to show in a detailed study that his estimates are clearly deficient in multi-centennial power, something that you actually did in your Perspectives piece, even if it was not clearly stated because of editorial cuts. It is puzzling to me that a guy as bright as Mike would be so unwilling to evaluate his own work a bit more objectively.

Subject: Re: AGU abstract

Date: Tue, 13 Aug 2002 10:16:42 +0100

Mike,

Checked with Keith and Tim. The abstract is like one we would write - leaves all options open as to what will be presented. At least AGU and EGS don't charge to get abstracts printed. AMS have so many missing now with their charges that the book of abstracts is ridiculous. Fine for all three of us to be there and we look forward to seeing some results in the autumn. This will be when the real action begins.

The CCDD meeting in early Nov. might be at a good time to discuss some results.

Add an 'of' between choice and actual on the third line.

Cheers

Phil

At 19:56 12/08/02 -0400, Michael E. Mann wrote:

Dear all,

The following is an abstract for a talk I've been invited to give at the winter AGU meeting in a session on "Climate of the Past 2000 Years". I would like to summarize the collaborative work that was begun by Scott, Tim and myself a couple summers ago during Tim's visit here. Scott is working on finalizing the results of our analyses now, and a draft should be available for review shortly that compares reconstructions based on our covariance-based reconstruction method, using (i) multiproxy, (ii) MXD, and (ii) combined multiproxy+MXD datasets for different (cold, warm, annual) target seasonal windows. I'd like to invite everyone listed below to be authors on both this abstract, and the paper that we're in the process of drafting, describing the results. I've kept the abstract intentionally vague, so that we can work out an interpretation of the results that we're all comfortable with in the months ahead, prior to the talk, and submission of the paper.

I look forward to confirmation of your interest in being a co-author, and any feedback you have. I'd like to submit this by the end of the week, which will be my last opportunity to do so prior to the AGU abstract deadline, owing to my travel schedule. thanks in advance for getting back to me ASAP.

best regards,

Mike

Progress in Proxy-Based Reconstruction of Surface Temperature Variations in Past Centuries

Michael E. Mann

Raymond Bradley

Keith Briffa

Malcolm Hughes

Philip Jones

Timothy Osborn

Scott Rutherford

Results are presented from a set experiments designed to control for the various factors that may influence reconstructions of large-scale temperature patterns in past centuries, including (a) the choice actual proxy data used, (b) the reconstruction methodology, (c) the spatial domain of the reconstruction and (d) the seasonal window targeted. These experiments compare results based both on the global multiproxy data set used by Mann and coworkers and the extratropical Northern Hemisphere maximum latewood tree-ring density set used by Briffa and coworkers. Estimates of hemispheric mean temperature trends are formed both through averaging of large-scale patterns reconstructed from full proxy data network, and through simple compositing of regional temperature reconstructions. Northern hemisphere mean estimates are compared for the full Northern hemisphere (tropics and extratropics, land and ocean), and extratropical continents only, and using various (cold-season half year, warm-season half year, and annual mean) seasonal targets for the reconstructions. Implications of these experiments for the robustness of proxy-based reconstructions of past large-scale temperature trends are discussed.

Reply-to: Rashit Hantemirov <rashit@ipae.uran.ru>

Dear Keith,
thank you very much for editing our paper.
It's a pity you strike your name off the list of authors, you
make an important contribution to writing paper. Your corrections
and additions surely improve paper.

I would only notice the next sentence (page 8):

'The low interannual variability and the minimum occurrence of
cold extremes during the 20th century, argue that the most recent
decades of this long summer record represent the most favourable
climate conditions for tree growth within the last four
millennia.'

I'm not sure that this statement follows unambiguously from results
presented in this paper. Because mean temperatures during last
decades, according to presented reconstruction, are not exceptional.
Besides, e.g. period about 1700 BC, according to this
reconstruction, represent probably the same conditions taking
into account low variability, low occurrence of extremes and high
mean temperature.

Maybe to soften this statement and replace 'the most favourable'
with something like 'highly favourably' or 'probably the most
favourable'?

Thank you once more for invaluable assistance.

Best regards,
Rashit M. Hantemirov

From: Mike Hulme <m.hulme@uea.ac.uk>
To: "Iain Brown (UKCIP)" <iain.brown@ukcip.org.uk>
Subject: Re: temporal interpolation for UKCIP scenarios
Date: Wed Sep 11 12:39:26 2002
Cc: geoff.jenkins@metoffice.com,x.lu.j.turnpenny

Iain (and Geoff),

Definitive explanations are always dangerous! The reasoning behind this is as follows:

- the report only analysed and pictured seasonal and annual data (DJF,MAM, etc.) [in fact, nearly all published maps of climate model outputs show changes in seasonal - 3-month - averages]. This applying a uniform filter over 90 or 360 days.
- the requested datasets are at monthly time-steps. The default option for this is in effect applying a uniform 30-day filter. [one might also conceive of weekly or daily time-step files - e.g. changes in Week 13 for the 2050s for precip. for Medium-High or changes for Julian day number 256 for the 2080s for Tmin for Low].
- these are all arbitrary choices of course, dictated by convention. But the important point it seems to me is again a signal to noise issue - the shorter the time-averaging period, the weaker the S/N ratio [i.e., we have more confidence that averaged over a year, Tmin in the UK will increase by, say, 2.7degC for certain scenario, than that for the same scenarios Tmin on 13 June will increase - on average - by 2.6degC and on 14 June only by 2.3degC - is this difference between 2.6 on 13 June and 2.3 on 14 June really meaningful? No - it is most likely due to noise - natural variability].
- this reasoning suggests that as the time-averaging period decreases, one should pay less attention to small differences between adjacent time-averaged periods, e.g. if June precip. goes down by 10%, is the fact that July precip. goes down by 20% and August by 5% really meaningful?

-

At 10:13 11/09/02 +0100, Iain Brown (UKCIP) wrote:

Mike,

For the UKCIP Scenarios datasets - both 98 and 02 - temporal interpolation was applied to the raw model data in the form of a 1-2-1 filter. This had the effect of smoothing out monthly values so that there are not as abrupt transitions between adjacent months.

Can you provide us with the definitive explanation for the interpolation?

Some users (eg. in the recent London study) have noted that there are differences between the maps they have derived from the data and the maps in the UKCIP02 report.

best wishes,

Iain

Gareth,

It seems to me, from reading your email, that you do not realize that this is precisely what MAGICC/SCENGEN already does -- i.e., it uses the scaling method that Ben Santer and I 'invented' in the late 1980s to get time dependent patterns of future climate change. I am attaching a description of the method as we employ it.

The current CDROM version uses only a SAR version of the UD-EBM. Of course, there is a TAR version that Sarah used for the TAR, developed by me and Sarah -- but mainly Sarah. This has not yet been put into MAGICC/SCENGEN, although I am in the process of doing so (along with making a number of other changes to the software). We do not normally give the code for TAR/MAGICC to others unless it is as part of a collaborative project. As Mike Hulme noted, what we can do for/with you will have to be a joint decision with me and Sarah.

The issue of how well scaling works compared with a full AOGCM is both important and of considerable interest to me (and Ben Santer). It is something we have looked at in the past, cursorily, and which we were planning to investigate more fully with the suite of PCM runs that we have here. There are some tricky issues that need to be addressed.

So, perhaps we should pool our intellectual, modelling and data resources?

Anyhow, check out the attached and get back to me with your views.

The 'new and improved version' of MAGICC/SCENGEN should be available in beta-test form in about a month. It will have around 30 models in its data base, and it does a lot of new things that I can tell you about later.

Tom.

Dear member of the extended board

The next ECF telephone conference takes place on Monday, 7 October 2002 at 17-18 CET (Central European Time). The participants are:

Gerhard Berz 089-3891 5290

Carlo Carraro +39-335-6170 775

Baldur Eliasson +41-58-586-8031

Jürgen Engelhard 0221-480 1460

Bill Hare 0331-288 2412

Klaus Hasselmann 04121-508 849

Jean-Charles Hourcade +33-1-43 94 73 63

Mike Hulme +44-1603-593162

Stephan Singer +32-2-74 38817

Carlo Jaeger 0331-288 2601

Martin Welp 0331-288 2619

Please check that your number is correct. If you want to be called at another number please inform me by the end of this week. In case there are technical problems at the beginning or during the conference please call the Deutsche Telekom at +49-(0)69-90922723.

The agenda is as follows (it may be modified at the beginning of the meeting):

1 Minutes of the previous telephone conference (5 Min.)

2 Working groups (10 Min.)

3 Meetings & Events (15 Min.)

- Report of the meeting with IEA (International Energy Agency)

- Report of the meeting with Vivendi Environnement Institute

- ECF general assembly (13 November)

- ECF conference in Berlin (14-15 November)

- Workshop of the Technology Group in Oldenburg (12-13 December)

4 Next steps (15 Min.)

5 Varia (15 Min.)

Best regards,

Martin Welp

Tom,

Talked to Tim re the SD field. Can you read the following (J. Climate 10, 2548-2568)

before you come so you know how Tim infilled the SD field ? HadCM2 data was used.

This would seem to bias any model validation to this model. Also it would seem odd to

validate any model in a region where there is no data - in a region that had to be infilled.

I can see that global fields make things simpler, but they will need to be constructed in

the best possible way. In 1997 we thought the best way was to use a model, but our aim then was different from yours.

Cheers

Phil

From: Gabi Hegerl <hegerl@duke.edu>

Subject: Re: paleo data

No worries, I can wait till next week!

It would be great to hear from you next week particularly if you feel I have overlooked something, I am planning to submit a little GRL paper on the detection results based on paleodata soon, and so a warning if I am doing something wrong would be great.

Its not surprising that the detection results are stable, since other than volcanic forcing is mainly driven by the low-f component anyway.

But it looks to me like the volcanic response is not smaller or even a bit larger in the annual JGR data (except for one real real big peak in the 1998 data).

Greetings, have a good weekend and good luck for Keith's back
Gabi

Gabi,

I have printed the files, but I do not know the answer. Keith is off today with a bad back -

seeing a chiropractor. I need to talk to him before we can reply. I will be away Mon/Tues

next week, so we will not be able to reply until later next week.

Cheers

Phil

At 11:27 31/10/02 -0500, Gabi Hegerl wrote:

Dear Keith and Phil,

I checked and found that we did indeed use the JGR 2001 data (by reloading them from your JGR data file). I also got the

1998 data from the volcano paper, and did some checking. My detection results appear quite unimpressed by if I filter the 2001 data to focus on lower frequencies or not (the estimated amplitudes of solar, volcanic and ghg signals are virtually identical, volcanism gets a bit tougher to detect if you remove the high-frequency component).

Then I redid the Epoch analysis comparing the

response of your data old and new to volcanism, and find somewhat bigger volcanic signals on average (using 50 eruptions between 1400 and 1940) in the JGR paper record. I high-passed both datasets and get somewhat more variability in the JGR record, not the 1998 record.

I am wondering is there something I am overlooking?

I append a figure of the high-passed (var > ca 10 yrs removed) records, and the volcanic response in both datasets (averaging years 1-20 after the eruption, and removing the best-estimate solar and ghg signal before the analysis).

The analysis omits years with another volcanic eruption within the 20 yrs.

I also append one version of the figure where the upper 95%ile of the ghg signal (which appears underestimated in Briffa 98 data) is removed rather than the best estimate, in that case, the volcanic signals in both data appear nearly identical.

Greetings, and please let me know if I am doing something wrong with your data!

Also, what is the best reference to a discussion on the difference between both datasets?

Thanks in advance

Gabi

Dear Tom

after a little detective work we have deduced that the data sent to you constitute a version of Northern Hemisphere Land temperatures (april- sept) produced by PCA regression using regional average density chronologies (ie the JGR paper you refereed I believe). It is true that high frequency component is not in my opinion optimal in describing the relative magnitude of extreme inter-annual extremes. This is to do with the unpredictable weighting ascribed to certain areas (tree-density series) in the averaging of the original raw data (this is boring and I won't go into it unless you really want me to). The relative differences in year-to-year values are likely better represented in the N.Hemisphere series produced by averaging regional series produced using a different approach in which the initial data are high-pass filtered and then merged in a more straight forward way. This is more equivalent to the series on volcanic signals described in our Nature paper, though the low-frequency component in this series is definitely not represented. There is another series , that one could consider a good compromise . That is a composite of the Age-Banding approach (JGR) low-frequency variance added to the earlier (Nature) high-frequency component. We did this for Figure 6 in the JGR paper , but did not provide the data on our web site I now realize. However this composite series is VERY highly correlated with the "better" high frequency data - see the correlations (Table 1 and related text in

[1]<http://www.cru.uea.ac.uk/cru/people/briffa/jgr2001/Briffa2001.pdf>

There are many possible ways of producing a "Northern Hemisphere" average , involving different prior regionalisation and secondary weighting (in space and through time) of the constituent series) . Non can be considered "correct". If you would like us to dig out the composite series or discuss specific aspects of the logic or uncertainties

associated with the different large averages let me know. Perhaps it would be better to discuss this on the phone? As for longer series, we can provide the 2000 year N.Eurasian data (a composite of ring width chronologies in N.Sweden, The Yamal peninsula, and Taimyr). I will soon be able to provide a 4000-year version, that is now being worked on.

or a similar Northern tree-ring chronology incorporating more data eg see

[2]<http://www.cru.uea.ac.uk/cru/people/briffa/qsr1999/>

We do not have the bristlecone data - but they are available I presume from the International Tree-Ring Data bank, part of the NGDC holdings?

At 02:29 PM 10/1/02 +0100, Phil Jones wrote:

Tom,

Been away and going again tomorrow. Had a chat with Keith and Tim and one of them will send a reply and data later this week.

Cheers

Phil

At 11:28 26/09/02 -0400, Tom Crowley wrote:

Hi Phil,

thanks for all your help on the bams paper

DOE is being exceedingly slow in processing the paperwork for our new round - I will keep you posted.

I am also wondering whether we can get some data from you:

Gabi is comparing our 2d ebm run with the briffa et al 2001 jgr time series in order to compare the model prediction of - I think you mentioned at one point something to the effect that, although this series is good for estimating low resolution temperature variability, it may dampen high frequency variability. if my memory is correct in this case, would you please send gabi the record you consider best for comparing with the model predicted interannual response to volcanic eruptions?

on another matter we are extending our runs back in time - I have now compiled a record of global volcanism back to 4000 BP for both hemispheres - extended back to 8000 BP for 30-90N. we are therefore trying to compile paleo records older than AD 1000 to at least get some reconstruction we can compare with.

I seem to recall that Keith or you may have published some longer reconstruction but cannot recall where it is? if so, would you be so kind as to send it to me? also I am trying to find a long record from the eastern California for the bristlecone pine - for some reason I am having difficulty finding one. if you have a long record - even going back beyond 2000 BP, it would be very much appreciated.

thanks for any help you can give us on this and best wishes, Tom

Dear Forumites -- Since I am neither a dendrochronologist nor a tree physiologist, I have a different take on this little brushfire we have going. Ideally, tree phys people should be producing information (among other things) that dendrochronologists find useful. And dendrochronologists should use the information within its limits and with enough understanding to get it right. I don't think either of those things is occurring with as much frequency as we would all like. I can understand Rod's annoyance at the massaging of numerical data that dendrochronologists do. I am basically a non-mathematical biologist mystified by such stuff, and I prefer handling measurements to deriving indices, or whatever. When I run up against such derived data, I generally turn skeptical, because I cannot verify the results from my own experience or intuition. On the other hand, when I read papers by cambial physiologists like Rod I also get annoyed. That's because my biology wants to integrate upwards, and all I get from cambial labs is biochemistry. So I'm in the middle, where it gets lonely. I try not to get mad at anybody, though I do wish I didn't find myself alone on the margins.

I find it frustrating that some dendrochronologists stubbornly see tree ring characteristics as being affected by climate. They are not. They are affected by cambial activity. Cambial activity is affected by internalities of tree behavior, mainly hormonal and nutrient fluxes in the crown. Those things are largely influenced by climatic factors. So there is quite a bit of slack between the climatic factor and the ring characteristic. Is this just negligible static? I doubt it. I see this as an oversight by dendrochronologists that weakens their credibility a tad among those knowledgeable about tree growth. I also have a quarrel with the dogma of dendrochology that the cambium changes as the tree becomes senescent. I know of no data that trees senesce -- that is, that they undergo changes due solely to aging. This started as forestry dogma, and was accepted by tree-ringers, who then corrected for it. I'm practically the only one who has systematically looked for evidence of senescence (with a Ph.D. student), and we could not find any in young to ancient bristlecones. But tree physiologists do not generally look at such issues because they have become progressively more reductionist. Nor do they try to produce a theory of tree growth based, as it must be, on evolutionary theory. Such a theory would be simple and general, and it would allow tree-ringers to approach rings with more sympathy and understanding. That might not get you further, but it would improve your character, I'm certain. And it would put all that assorted mishmash of tree phys data that have accumulated since 19th century Germany into a context at last, and maybe liberate the minds of all those tense physiologists out there with their ever-increasing inventories of electronic sensors and analyzers. The world would be a better place with more people having

fun in the woods.

Dear Professor Savidge, Hal Fritts's comments were, as always, to the point and gracious. I have much less patience with your ignorance and arrogance. The sampling and statistical procedures involved in the production of a cross-dated chronology are of course quite different to those used in a randomised experiment, but they are none-the-less logical, rigorous, science. We have been through all those arguments so many times - you are wasting everyone's time.
John Ogden.

Subject: Re: Fw: Fw: Reconstruction etc.
Date: Sat, 23 Nov 2002 00:01:30 +0300

Dear Keith,

Do not be embarrassed. This situation is very humorous and I am very glad to smile. It happens.

Thank you very much for your time series.

I would like to analyse spectra characteristics of summer temperatures (your series) and winter temperature series using Dansgaard's time series for the same period (since 550s). It seems to me the temperature data of Arctic basin is the most pronounced indices illustrating of long term climate oscillations.

Best wishes

Leonid

Subject: Re: Fw: Fw: Reconstruction etc.

I am very embarrassed as I have just realized I sent the data (a couple of weeks ago at least !) to the wrong person (someone called Leonid Polyak) by mistake. He wanted polar Urals data. I now attach the file with the Nature temperature reconstruction.

First number is the number of values , then subsequent lines contain the date in the first column (years AD) and the anomalies in the second (as described in the paper).

Sorry!!!!!!!!!!!!!!!!!!!!

Keith

At 10:45 PM 11/18/02 +0300, you wrote:

Dear Keith,

I apologise for persistens but I really need in the time series I requested from you and I will very grateful to you for these materials which you so kind promised send to me .

I hope receive it from you yet, although I have not reply from you to my two last messages.

Yours sincerely

Leonid

Sorry not to respond

I will search out the tree-ring series (ring width and density) and the numbers for the reconstruction and send them as soon as I can get to it. Remind me in a couple of days if they do not arrive. Cheers

Keith

At 02:17 PM 10/22/02 +0400, you wrote:

Dear Dr Briffa,

Unfortunately I did not receive reply on my first message sent to your address by October 8.

I apologize for disturbing you again but I will be very grateful to you for sending me the address of web site where I can find the data of tree ring reconstruction of the summer temperature.

I also very interested in receiving data published in one of your et al. old paper: "A 1400 year tree ring record of summer temperature in Fennoscandia,1990, Nature.vol 346, 2 August 1990."

The time series of Pinus silvestris published at Fig 2 a is very interesting for my work on the dynamics climate-linked fisheries of Northern Hemisphere.

I would be very grateful to you for your reply.

Best regards
Leonid Klyashtorin

----- Original Message -----

From: [7]L.B. Klyashtorin
To: [8]Briffa Keith R.
Sent: Tuesday, October 08, 2002 4:58 PM
Subject: Fw: Reconstruction etc.

I am Leonid Klyashtorin from Federal Institute for Fisheries and Oceanography (VNIRO),Moscow,Russia.

The last 6 monthes I was National Research Council Senior

Associate and worked as Visiting Scientist in the Pacific Fisheries Environmental Laboratory (PFEL), NOAA, National Marine Fisheries Service, Monterey, CA on the item "Climate and Fisheries".

My paper "Climate change and long-term fluctuations of commercial catches: the possibility of forecasting" published recently as a separate brochure, FAO Fisheries Technical Paper No 410,

pp 86, 2001, and is rather popular among fisheries specialists.

It gives insight of world major fisheries dynamics and contains forecast to the next 10-20 years. (The Abstract is attached, PDF file of all paper also is available)

I have read of your and T. Osborn very interesting and so useful paper "Blowing Hot and Cold.." in Science, v.295.,2002.

Your results clearly shows that main conception of IPCC experts about unicity of Global Warming events in 20-century is erroneous and now the additional data appear on the natural long term cyclic climate change at least for the last 2000 years.

My work on the "Climate - Fisheries" connected with questions of Climate Change and, naturely, touches of Global Warming Problem.

Me and my colleague from Institute of Physics of the Earth of Russian Academie of Science recently submitted our paper "On the coherence between dynamics of the world fuel consumption and global temperature anomaly". in the International Journal "Natural Hazards".

The paper is now under reviewing. (The Abstract is attached.)

Now me and a few my colleagues from US are in process of writing book dedicated of Climate- Fisheries problem and we would like use the data on the tree-rings analysis showing cyclic character of long-term climate changes.

I will be very grateful to you for receiving from you (if possible) the time series of annual reconstructed temperature anomaly from Figure (Esper02) and address of website, where these data are available.

Thank you in advance

Best regards
Leonid Klyashtorin

Subject: UK Research Office - FP6 Proposal Writing for Researchers

Date: Tue, 26 Nov 2002 18:34:49 +0000

Cc: j.darch@uea.ac.uk

Dear all

I went to this meeting in London yesterday - which was useful. Julie will photocopy my notes/the overheads for you some time this week (if she doesnt have time, I'll do it when I get back next week). In the meantime, here are my main impressions/thoughts from the meeting. (Incidentally, Alex Haxeltine was due to go from UEA, but didnt turn up. Not sure who the other UEA people were! There was no list of participants.) Maybe we should get together (next week some time?) once you've had chance to look at some of this.

The Commission (EC) seems to be favouring smaller projects, e.g., typically 10 million Euro. Though it is up to proposers to define the necessary 'critical mass'.

UKRO seem quite wary of Networks of Excellence (NoE), e.g., warning of potential conflicts of interest with institutions. As with projects, smaller size seems to be in favour. An UKRO analysis suggests an NoE of 150-400 researchers would maximise the amount of money received per researcher.

Research activities can now be funded in NoE (the EC has changed its mind on this in the last month), but only if focused on integration.

The EC wont be proposing indicators of integration for NoE - the proposals should explain how this will be 'measured'.

Consortium quality seems to be an important concern for the EC, i.e., having the right people for the job and ensuring everyone has a clear role. In our rush to get a 'critical mass', I'm concerned that the GENIE consortium may appear too much as 'all our friends'. One possible strategy which UKRO seemed to think quite good for people, would be to put in a proposal from 6-8 key partners, indicating for which activities additional partners will be brought in at appropriate points. The EC will be providing formal procedures for these 'internal project' calls.

It is unlikely that the new online proposal preparation tool will be ready for the first call, but electronic submission (on CD) should be possible. Any paper submissions will be scanned.

Evaluation will be by electronic means initially, with possibility of proposers (and evaluators?) being invited to hearings in Brussels prior to panel meetings.

No signatures are required for the proposals (though a password/username will be required by co-ordinators to access the online system). Some institutions/consortia are apparently drawing up pre-consortia agreements or letters of intent/memorandum of understanding.

The guide for proposers is currently only in very rough draft.

There will be a second 'EOI' type exercise at the end of 2003/early 2004. This could lead to changes in the indicative themes for 2004.

UKRO is not keen on UK institutions using consultants for project management - we should be

building our own capacity.

Proposals should be written for the informed lay person. It is best if they are not obviously written by one person - better to show joint effort/co-ordination at an early stage.

Redundancy costs (i.e., costs of implementing the new fixed-term regulations) can be included for research staff.

The EC aims to audit all FP6 projects (because there will be fewer of them).

Recognition of the ERA and policy links will be important for the EC. (The ERA includes references to developing long-term careers for research staff and increasing the involvement of women - so maybe we should be thinking of some activities to address these issues.)

IPR will be an important issue in FP6 - need to get expert advice (e.g., what happens if consortium changes over course of project).

Consortium agreements will be compulsory.

The proposal forms (for IPs anyway) are relatively simple, e.g., only need to cost four different types of activity.

<x-flowed>
Dear friends,

I assume many of you have followed the development of the work programme for FP6, which have been quite dramatic at times for our field. The end result is not particularly good, and the whole area of Global Change has been cut by comparuison with FP5. I talked with Anver Ghazi last week, and what I know stems from this and from the Nov. 18 version of the work programme. The will be no opening for climate dynamics in the first call (Dec. 17). The second call due in June /July with a deadline in October 2003 will include some paleoclimate openings:

- STREPS for novel paleoreconstructions methods (i.e. a few of the normal projects of previous FPs) - but remember: 75% of funding goes to New Instruments: Integrated Projects and NoEs).
- Hot spots in the climate system, including the thermohaline circulation and the Arctic.

Brussels will not issue anything now about the thrird call, but according to Ghazi they plan to invite for either an NoE or an IP in climate dynamics with emphasis on past climate change at that point. Call will be in 2004. But things can change with this call. Thus we have quite some time to discuss if we shall go forward with DOCC or go for IP. The overall size of the IPs have been substantially reduced, so if we try an IP or an NoE either will need to be more focussed in terms of science and in terms of partnership than our Expression of interest.

Ceers,

Eystein

Subject: Climate Change Funding in Scotland
Date: Mon, 2 Dec 2002 15:09:24 -0000

Dear John and Mike

It was over two years ago that we first briefly discussed the opportunity to develop climate change research funding in Scotland using a grant to HEI's from the Scottish Higher Education Funding Council (SHEFC). My Centre, CECS, has been successful with such grants in the past. Last year there were no such grants but the opportunity has now arisen again. The funding is quite large (0.5 - 1.5 million over up to 4 years). With support from the three main agencies in Scotland I am keen to develop such a research proposal and will be entering the internal competition (within the University) shortly.

I am keen to develop a strong link/cooperation with the Tyndall Centre and I would like to explore ways in which this might be achieved. Last week I believe that you were busy with your Advisory Board. I would be very keen to talk with you on the phone about this as soon as possible. Please let me know if there is a suitable time when I might phone or feel free to contact me.

Best wishes

Andy

Thanks very much Tim,

Your comments are extremely helpful.

I'm open to eliminating the comparison w/ Esper et al --but lets see if there is a consensus of the group as to what to do here. We're anxiously awaiting comments from the others...

thanks again,

mike

p.s. Scott can be reached at either U.Va or U.RI email equally well (I believe the former is forwarded to the latter)..

At 12:16 PM 1/6/2003 +0000, Tim Osborn wrote:

Dear Scott and Mike,

Over the Christmas break I (finally!) had time to read the RegEM manuscript in detail. Phil had already read and annotated a copy - so I've added my annotations to that and will mail it to you today. Mike asked for comments to go to Scott, so please tell me which address I should use (Rhode Island or Virginia?).

I spoke to Keith and he has partly read it too, and will provide separate comments soon.

Overall, I think the paper is a very nice piece of work and I'm pleased to be involved with it. The results regarding robustness with respect to proxy data, method, region and season are definitely good to publish.

Among the many comments annotated on the manuscript, a few are repeated here so that all authors may respond if they wish:

(1) Given the overwhelming number of values in the Tables, I suggest halving them by dropping all the CE values (keeping just RE values). As the paper points out, getting the verification period mean right is rewarded by RE but not by CE. Since we are interested in changes in the mean, I don't think that's a problem. CE is fine in addition, but dropping it would provide benefits of reducing manuscript size - and especially the size of the tables.

(2) The "mixed-hybrid" approach sounds dubious to me - more justification/explanation of why it is needed (and hence why it captures more variance than the simpler splitting into high- and low-frequency components method).

(3) It is not clear to me that the paragraph and figure on the comparison with Esper et al. are either correct or necessary. They also are problematic because it would appear that we (Briffa & Osborn) were contradicting our earlier paper when in fact we aren't. The paper is already long and to remove these parts would therefore be helpful anyway. The comparison with Esper et al. is important - but much better dealt with in a separate paper where it could be developed in more detail and with more room to explain the approach and its implications.

(4) I still hope to write up some more detailed comparisons of the reconstructions using just the MXD data but different methods and will let Mike/Scott know my plans on this soon.

Happy new year to you all.

Tim

<x-flowed>

Tim,

As promised some comments on the paper.

General: It is very good, just what is needed and puts the last 4 years of debate into the right context.

General: why consistently 'climate changes' rather than the more usual 'climate change'?

Abstract, line 10: why only quote as high as 0.99 and not the lowest correlation (which actually is more to the point - it is still very good after the 2020s, even for precip).

Abstract, lines 12-13: as worded this does not quite follow, although I see from later that the ellipses used are at 95% confidence. Just because they fall outside natural variability does not *in itself* prove they are stat. sig.

p.2, lines 17-19 (and also several places on p.4): impacts are mentioned, but nothing said about adaptation. It is really adaptation actions/decisions that are crucial, impacts are only one way to get there. Alter the focus.

p.2, line -10: add 'necessarily' between 'not' and 'be'. AOGCMs may actually do not so bad a job on occasions about climate change (relative changes for example), so don't completely dismiss this one.

p.5, section 2: general point: there is no list or table or statement about exactly what these 17 experiments are. The models are listed, but not the experiments. e.g. which SRES scenarios did which modelling group and how many ensembles? For the lay person this is not obvious.

p.7, top line: you should perhaps make the point that simple bias indices such as these may partly be explained by elevation offsets (model height vs. real height). It is to my mind a mitigating factor than can work in a model's favour (not always). It should be mentioned, because the biases

may not be due to just dumb models, but due to simple resolution issues that can be adjusted easily. A similar point perhaps applies in the next para. about ocean/land boundaries. OK, you could say this just shows how bad models are, but it perhaps gives people a poorer view of the model physics and credibility than is truly needed. Another point to mention in this para about precip. is the obvious point about decadal natural variability. It's a tall order to expect the models to get the 1961-90 monthly mean precip. exactly right, owing to internal variability. Indeed, give such variability can be plus/minus 10-20% or more it would be astonishing if they matched. Be generous to models I say.

p.9, middle - interesting point about ECHAM4 and NCAR masks!!

p.15, para 2: didn't you have A1FI available from Hadley? Surely it could have been used to test this? Last sentence in this para: why 'evidently conform'?

p.16, last line: interesting point here: if you claim the pattern-scaling didn't work for the 2020s because of nat var (S/N ratios) then why actually should we go with the raw model results anyway - certainly if it is the signal we are interested in (and not the noise), it suggests the raw 2020s models results are misleading us! This is a rather circular argument I realise but the bottom line point again comes back to S/N ratios and the role of nat decadal variability, esp. for precip. Are we going to recommend adaptations to noise or to signals - and why?

p.17, middle para: what about mentioning climate sensitivity here? I know its out of vogue now, but PCM and NIES differences are explained by overall model sensitivity aren't they.

p.17, para 4: this point about where agreement occurs between models is important. Some people - I heard Wigley do it recently - write models off at regional scales re. precip changes because they all disagree. They do for some regions, but not all and where we think we have physical grounds to accept agreement as legit. (e.g. UK; cf. UKCIP02 scenario methodology) then we should be confident to say so.

p.17, line -7: why use 'forecasting' here? Could confuse some people. The old argument about terms I guess. And again top line on p.18 is dangerous - we can "predict" nat. variability in a stochastic sense using ensembles. Change the wording.

p.18, line 9: not only are they difficult to foresee, they are simply

unforseeable to a significant extent because it is we who determine them; I prefer to make the distinction between different types of prediction problem more explicit.

p.18, lines 19-20: I don't like the use of 'truth' and 'precise' here. It implies a strong natural science view prediction and the competence of science (modellers!) which I think should be softened.

p.18, para 4: the inter-model differences bit being as large as the inter-scenario differences. Again at least mention the role of nat var here - some of these inter-model differences **must** be due to nat var, not simply models not able to agree with each other.

p.19, para 1: I think the stabilisation case should be mentioned here. What about pattern-scaling stab scenarios? As I hear it from DEFRA and Hadley here in UK this was a big issue at the TGCIA meeting. Make a comment at least; I think in principle p-scaling is probably OK (within some limits) even here. I think you should make reference to some of Tim Mitchell's work here (and/or elsewhere) since he has looked at some of these things too. His thesis or his CC paper perhaps.

And finally, w/o sounding as self-serving as Tom Wigley, it would be nice if you could reference (perhaps in section 3.3) the Hulme/Brown (1998) paper in CR which was the first time I published scatter plots in this form for GCMs results - and possible the first time this form of presentation had been used anywhere (but I stand corrected of course; maybe I simply picked it up from someone else).

So there it is: a great piece of work and a good write up. I don't know Kimmo but pass on my congratulations to him. I'll look out for it on the web site.

Best wishes,

Mike

Dear Ulrich,

That's fine--you can go ahead and use it. But I have to issue a number of caveats first.

This is a version we gave Tim Osborne when he was visiting here, and since Tim hasn't used it, and we haven't compared results from that code w/ our published results, I can't vouch for it--it may or may not be the exact same version we ultimately used, and it may or may not run properly on platforms other than the one I was using (Sun running ultrix). Scott Rutherford (whom I've cc'd on this email) has worked with the code more frequently. The code is not very user friendly unfortunately. For example, the determination of the optimal subset of PCs to retain is based on application of the criterion described in our paper, which involves running the code many times w/ different choices. So the "iterative" process has to be performed by brute force.

The method, as outlined, is quite straightforward and others have implemented it themselves. SO you might prefer to code it yourself. That would be my suggestion. But you are, of course, free to use our code.

That having been said, we have essentially abandoned that method now in favor of a somewhat more sophisticated version of the approach, which makes use of the RegEM method for imputing missing values of a field described by Schneider (J. Climate, 2000).

Some initial results are described here:

Mann, M.E., Rutherford, S., Climate Reconstruction Using 'Pseudoproxies', Geophysical Research Letters, 29 (10), 1501, doi: 10.1029/2001GL014554

[1][ftp://holocene.evsc.virginia.edu/pub/mann/Pseudoproxy02.\[2\].pdf](ftp://holocene.evsc.virginia.edu/pub/mann/Pseudoproxy02.[2].pdf)

and in a paper in press in Journal of Climate.

Rutherford, S., Mann, M.E., Delworth, T.L., Stouffer, R., The Performance of Covariance-Based Methods of Climate Field Reconstruction Under Stationary and Nonstationary Forcing, J. Climate, in press, 2003.

(I don't have the preprint--Scott Rutherford can provide you with one however).

In our view, this is a preferable approach on a number of levels, though the results obtained are generally quite similar.

I will be in Nice, and looking forward to seeing you there,

Mike

At 04:59 PM 1/28/03 +0100, Ulrich Cubasch wrote:

Dear Michael,

as you might know we (Briffa, Wanner, v. Storch, Tett ...) have an European project called SOAP, which aims at combining multy proxi and model data.

more under [3]<http://www.cru.uea.ac.uk/cru/projects/soap>

In the workpackage I am coordinating we would like to use your multi-proxy program for some

temperature reconstructions. The colleagues in Norwich have got your program already, but I would like to implement it here in Berlin. I therefore would like to ask you if you can grant me the permission to use it.

I will probably copy it then from Keith and Tim directly.

I will keep you informed about the results we obtain with it.

regards

Ulrich Cubasch

Dear Irina,

The code we used in Mann/Bradley/Hughes 1998 was not changed or "improved", but there may be different versions of the code floating around, and in a previous email to Uli Cubasch, I indicated that I was not sure the version you have (from Tim Osborn), is identical to the version we used in our original paper (it would require some work on my part to insure it gives precisely the same results, and I don't have the time to do that). I suspect, however, that the code is the same as the one we used in our paper and any differences, if they exist, should be minor (as long as the code compiles and runs correctly on the platform you have--the possible platform-dependence of fortran is a potential cause for concern here).

Numerous people have coded up our method independently, including Ed Zorita, w/ whom I believe your group has a close collaboration, and my graduate student Zhang has successfully coded this up independently in Matlab (its a short script, which didn't take Zhang long to write anyway). I'm copying this message to Zhang, so that he can provide you with his matlab version of the code if you are interested. Because Zhang's version is in Matlab, it should run correctly, independently of the particular platform (an advantage over the fortran code) [As an aside, on a pedagogical note, I would still encourage you to code this up yourself].

As I indicated in a previous email to Uli, the selection of the optimal subset of EOFs to retain is not automated in the code, and you need to do that yourself...The methodology we used is described in detail in our publications.

We have tested this method against the approach our group now uses for climate field reconstruction (Schneider RegEM approach), and find that the results are similar, but the cross-validation statistics improve slightly w/ the RegEM approach, which we now favor and use in place of the old, Mann et al approach.

Details of this latter approach are described in these two manuscripts (as well as the original paper by Schneider referenced within):

Mann, M.E., Rutherford, S., Climate Reconstruction Using 'Pseudoproxies', Geophysical Research Letters, 29 (10), 1501, doi: 10.1029/2001GL014554, 2002.

available at:

[1][ftp://holocene.evsc.virginia.edu/pub/mann/Pseudoproxy02.\[2\].pdf](ftp://holocene.evsc.virginia.edu/pub/mann/Pseudoproxy02.[2].pdf)

Rutherford, S., Mann, M.E., Delworth, T.L., Stouffer, R., Climate Field Reconstruction Under Stationary and Nonstationary Forcing, Journal of Climate, 16, 462-479, 2003.

available at:

[3]<ftp://holocene.evsc.virginia.edu/pub/mann/Rutherfordetal-Jclim03.pdf>

The RegEM code is available over the web, and Scott Rutherford can provide you with the ftp side if you are interested. It, too, is available only in matlab.

I hope you find this information of help.

Best of luck w/ your research,

mike mann

At 06:10 PM 2/5/03 +0100, Irina Fast wrote:

Dear Michael,

I believe that you have not heard about me as yet. My name is Irina Fast.

Since the January 2003 I am a PhD student at the Free University in Berlin in

the framework of the EU-Project SOAP. My supervisor is Ulrich Cubasch.

At the SOAP's start-up meeting it was proposed to use your multiproxy calibration method (published in 1998) for the joint analysis of model simulations and proxydata.

Because your method was essential improved since 1998 I would like to know if you kann provide us with your program code.

We could try to code your approach ourselves, but we do not know if this kind of analysis will success in our case. In the case of failure we will have to search for other analyses methodes. And the timespan for the data processing is rather short. Naturally you will not miss our gratitude and acknowledgement.

I apologise for my mistakes in this letter.

Best regards

Irina Fast

At 14:07 12/02/03 +0100, Kabat, dr. P. wrote:

Dear Mike, John, Alex:

referring to our tel. conversation yesterday with Alex, hereby our request for a letter of support/recommendation on behalf of Tyndall for our national Global Change Initiative programme proposal called "Climate changes the spatial planning", ("Climate for Spatial Planning Spatial Planning for Climate); unofficially known to you I guess as "Netherlands Tyndall-like initiative...)

After we have successfully passed the first round of the selection last year with the Dutch Government, we are now in final stages of submitting the final proposal/business plan (deadline 17/2/03 - next Monday).

The proposed programme has a total budget of 100 million Euro, of which 49 million is requested from the Government, rest contribution of public and private institutions. As a part of this programme we are aiming to set up Netherlands Centre of Excellence (partly virtual) institute, modelled after Tyndall. Leading parties in this effort are all well known to you:

Wageningen (kabat)

VU Amsterdam (vellinga)

RIVM (metz)

KNMI (Komen)

ICIS (Rotmans)

ECN (Bruggink)

plus another almost 50 parties.

Could you pls send us a short letter of support, in which you indicate the importance of this initiative for advancing this type global change science, European dimension, UK - NL collaboration, etc, etc?

We need to receive this by Friday, so send also by fax pls (apologies for the rush). Letter is to be addressed as follows:

Prof. Dr Pavel Kabat

Science Director

Netherlands National Research Initiative "Climate changes the spatial planning", (ICES KIS 3)

Postal address: PO Box 47, 6700 AA Wageningen

Visiting address: Lawickse Allee 11, IAC building, room 156

Voice +31 317 474314/74713 (office), +31 653489378 (mobile), +31 264463567
(home);

Fax: +31 317495590

I attach 3 documents as background of our proposal

Many thanks for your kind help!

Pavel, Pier en colleagues

Subject: Re: AMS proposal
Date: Mon, 10 Mar 2003 17:36:46 -0000

Dear Colleagues,

In the email from Armin Haas (signed by Carlo and Klaus) on 5th March, we were informed that a strategy committee and a research committee had been formed; with the latter being primarily responsible for the preparation of the proposal.

WE NOW HAVE ONLY 20 WORKING DAYS LEFT UNTIL THE PROPOSAL HAS TO BE SUBMITTED!!!

And while I am aware and involved in a number of parallel activities addressing the writing of text for specific work domains and work packages, I have not received any formal communication about what role is expected of me as a member of the research committee (that has primary responsibility for the preparation of the proposal).

Needless to say I find this extremely worrying, and suggest that we URGENTLY need clarification about 1) exactly what the research committee should do; 2) how it should do it; 3) what responsibility for making decisions this committee will have/how it should liaise with the strategy committee.

It seems clear that in order to finalize an overall project structure we will need to meet face-to-face for at least 36 hours, and that this needs to happen with the utmost urgency.

I have made a provisional booking of a facility very near Stanstead airport in the UK for

next Monday and Tuesday (17th and 18th March), and offer this as a possible time and place

to meet; but am of course open to other suggestions. I would imagine that in addition to

the research committee assigned so far, we would need to co-opt the writers of several of

the work packages and the work domains leaders for the purpose of this meeting.

With warm regards and the utmost sense of urgency,

Alex Haxeltine

Thanks Phil,

(Tom: Congrats again!)

The Soon & Baliunas paper couldn't have cleared a 'legitimate' peer review process anywhere. That leaves only one possibility--that the peer-review process at Climate Research has been hijacked by a few skeptics on the editorial board. And it isn't just De Frietas, unfortunately I think this group also includes a member of my own department...

The skeptics appear to have staged a 'coup' at "Climate Research" (it was a mediocre journal to begin with, but now its a mediocre journal with a definite 'purpose').

Folks might want to check out the editors and review editors:

[1]<http://www.int-res.com/journals/cr/crEditors.html>

In fact, Mike McCracken first pointed out this article to me, and he and I have discussed this a bit. I've cc'd Mike in on this as well, and I've included Peck too. I told Mike that I believed our only choice was to ignore this paper. They've already achieved what they wanted--the claim of a peer-reviewed paper. There is nothing we can do about that now, but the last thing we want to do is bring attention to this paper, which will be ignored by the community on the whole...

It is pretty clear that thee skeptics here have staged a bit of a coup, even in the presence of a number of reasonable folks on the editorial board (Whetton, Goodess, ...). My guess is that Von Storch is actually with them (frankly, he's an odd individual, and I'm not sure he isn't himself somewhat of a skeptic himself), and without Von Storch on their side, they would have a very forceful personality promoting their new vision.

There have been several papers by Pat Michaels, as well as the Soon & Baliunas paper, that couldn't get published in a reputable journal.

This was the danger of always criticising the skeptics for not publishing in the "peer-reviewed literature". Obviously, they found a solution to that--take over a journal! So what do we do about this? I think we have to stop considering "Climate Research" as a legitimate peer-reviewed journal. Perhaps we should encourage our colleagues in the climate research community to no longer submit to, or cite papers in, this journal. We would also need to consider what we tell or request of our more reasonable colleagues who currently sit on the editorial board...

What do others think?

mike

Dear All,

Apologies for sending this again. I was expecting a stack of emails this morning
in

response, but I inadvertently left Mike off (mistake in pasting) and picked up Tom's old address. Tom is busy though with another offspring !

I looked briefly at the paper last night and it is appalling - worst word I can think of today without the mood pepper appearing on the email ! I'll have time to read more at the weekend as I'm coming to the US for the DoE CCPP meeting at Charleston. Added Ed, Peck and Keith A. onto this list as well. I would like to have time to rise to the bait, but I have so much else on at the moment. As a few of us will be at the EGS/AGU meet in Nice, we should consider what to do there.

The phrasing of the questions at the start of the paper determine the answer they get. They have no idea what multiproxy averaging does. By their logic, I could argue 1998 wasn't the warmest year globally, because it wasn't the warmest everywhere. With their LIA being 1300-1900 and their MWP 800-1300, there appears (at my quick first reading) no discussion of synchronicity of the cool/warm periods. Even with the instrumental record, the early and late 20th century warming periods are only significant locally at between 10-20% of grid boxes.

Writing this I am becoming more convinced we should do something - even if this is just to state once and for all what we mean by the LIA and MWP. I think the skeptics will use this paper to their own ends and it will set paleo back a number of years if it goes unchallenged.

I will be emailing the journal to tell them I'm having nothing more to do with it until they rid themselves of this troublesome editor. A CRU person is on the editorial board, but papers get dealt with by the editor assigned by Hans von Storch.

Cheers

Phil

Dear all,

Tim Osborn has just come across this. Best to ignore probably, so don't let it spoil your day. I've not looked at it yet. It results from this journal having a number of editors. The responsible one for this is a well-known skeptic in NZ. He has let a few papers through by

Michaels and Gray in the past. I've had words with Hans von Storch about this, but got nowhere.

Another thing to discuss in Nice !

Cheers
Phil

Dear All,

I like Phil's suggestion. I think such a piece would do a lot of good for the field. When something as full of half-truths/mis-truths as the S&B piece is put forth, it would be very useful to have a peer-reviewed review like this, which we all have endorsed through co-authorship, to point to in response. This way, when we get the inevitable "so what do you have to say about this" from our colleagues, we already have a self-contained, thorough rejoinder to point to. I'm sure we won't all agree on every detail, but there is enough commonality in our views on the big issues to make this worthwhile.

Perhaps Phil can go ahead and contact the editorial board at "Reviews of Geophysics" and see if they're interested. If so, Phil and I (and anyone else interested) could take the lead with this, and then we can entrain everyone else in as we proceed with a draft, etc.

mike

p.s. Keith: I hope you're feeling well, and that your recovery proceeds quickly!

At 10:02 AM 3/12/2003 +0000, Phil Jones wrote:

Dear All,

I agree with all the points being made and the multi-authored article would be a good idea, but how do we go about not letting it get buried somewhere. Can we not address the misconceptions by finally coming up with definitive dates for the LIA and MWP and redefining what we think the terms really mean? With all of us and more on the paper, it should carry a lot of weight. In a way we will be setting the agenda for what should be being done over the next few years.

We do want a reputable journal but is The Holocene the right vehicle. It is probably the best of its class of journals out there. Mike and I were asked to write an article for the EGS journal of Surveys of Geophysics. You've not heard of this - few have, so we declined. However, it got me thinking that we could try for Reviews of Geophysics. Need to contact the editorial board to see if this might be possible. Just a thought, but it certainly has a high profile.

What we want to write is NOT the scholarly review a la Jean Grove (bless her soul) that just reviews but doesn't come to anything firm. We want a critical review that enables agendas to be set. Ray's recent multi-authored piece goes a lot of the way so we need to build on this.

Cheers

Phil

At 12:55 11/03/03 -0500, Michael E. Mann wrote:

Hi Malcolm,

Thanks for the feedback--I largely concur. I do, though, think there is a particular problem with "Climate Research". This is where my colleague Pat Michaels now publishes exclusively, and his two closest colleagues are on the editorial board and review editor board. So I promise you, we'll see more of this there, and I personally think there *is* a bigger problem with the "messenger" in this case...

But the Soon and Baliunas paper is its own, separate issue too. I too like Tom's latter

idea, of a more hefty multi-authored piece in an appropriate journal (Paleoceanography? Holocene?) that seeks to correct a number of misconceptions out there, perhaps using Baliunas and Soon as a case study ('poster child?'), but taking on a slightly greater territory too.

Question is, who would take the lead role. I *know* we're all very busy,
mike

At 10:28 AM 3/11/03 -0700, Malcolm Hughes wrote:

I'm with Tom on this. In a way it comes back to a rant of mine to which some of you have already been victim. The general point is that there are two arms of climatology:

neoclimatology - what you do based on instrumental records and direct, systematic observations in networks - all set in a very Late Holocene/Anthropocene time with hourly to decadal interests.

paleoclimatology - stuff from rocks, etc., where major changes in the Earth system, including its climate, associated with major changes in boundary conditions, may be detected by examination of one or a handful of paleo records.

Between these two is what we do - "mesoclimatology" - dealing with many of the same phenomena as neoclimatology, using documentary and natural archives to look at phenomena on interannual to millennial time scales. Given relatively small changes in boundary conditions (until the last couple of centuries), mesoclimatology has to work in a way that is very similar to neoclimatology. Most notably, it depends on heavily replicated networks of precisely dated records capable of being either calibrated, or whose relationship to climate may be modeled accurately and precisely.

Because this distinction is not recognized by many (e.g. Sonnechkin, Broecker, Karlen) we see an accumulation of misguided attempts at describing the climate of recent millennia. It would be better to head this off in general, rather than draw attention to a bad paper. After all, as Tom rightly says, we could all nominate really bad papers that have been published in journals of outstanding reputation (although there could well be differences between our lists).

End of rant, Cheers, Malcolm

> Hi guys,

>

> junk gets published in lots of places. I think that what could be done is a short reply to the authors in Climate Research OR a SLIGHTLY longer note in a reputable journal entitled something like "Continuing Misconceptions About interpretation of past climate change." I kind of like the more pointed character of the latter and submitting it as a short note with a group authorship carries a heft that a reply to a paper, in no matter what journal, does not.

Phil et al,

I suggest either BAMS or Eos - the latter would probably be better because it is shorter, quicker, has a wide distribution, and all the points that need to be made have been made before.

rather than dwelling on Soon and Baliunas I think the message should be pointedly made against all of the standard claptrap being dredged up.

I suggest two figures- one on time series and another showing the spatial array of temperatures at one point in the Middle Ages. I produced a few of those for the Ambio paper but already have one ready for the Greenland settlement period 965-995 showing the regional nature of the warmth in that figure. we could add a few new sites to it, but if people think otherwise we could of course go in some other direction.

rather than getting into the delicate question of which paleo reconstruction to use I suggest that we show a time series that is an eof of the different reconstructions - one that emphasizes the commonality of the message.

Tom

Dear All,

I agree with all the points being made and the multi-authored article would be a good idea, but how do we go about not letting it get buried somewhere. Can we not address the misconceptions by finally coming up with definitive dates for the LIA and MWP and redefining what we think the terms really mean? With all of us and more on the paper, it should carry a lot of weight. In a way we will be setting the agenda for what should be being done over the next few years.

We do want a reputable journal but is The Holocene the right vehicle. It is probably the best of its class of journals out there. Mike and I were asked to write an article for the EGS journal of Surveys of Geophysics. You've not heard of this - few have, so we declined.

However, it got me thinking that we could try for Reviews of Geophysics. Need to contact the editorial board to see if this might be possible. Just a thought, but it certainly has a high profile.

What we want to write is NOT the scholarly review a la Jean Grove (bless her soul) that just reviews but doesn't come to anything firm. We want a critical review that enables agendas to be set. Ray's recent multi-authored piece goes a lot of the way so we need to build on this.

Cheers

Phil

At 12:55 11/03/03 -0500, Michael E. Mann wrote:

HI Malcolm,
Thanks for the feedback--I largely concur. I do, though, think there is a particular problem with "Climate Research". This is where my colleague Pat Michaels now publishes exclusively, and his two closest colleagues are on the editorial board and review editor board. So I promise you, we'll see more of this there, and I personally think there *is* a bigger problem with the "messenger" in this case...

But the Soon and Baliunas paper is its own, separate issue too. I too like Tom's latter

idea, of a more hefty multi-authored piece in an appropriate journal (Paleoceanography?

Holocene?) that seeks to correct a number of misconceptions out there, perhaps using

Baliunas and Soon as a case study ('poster child'?), but taking on a slightly greater territory too.

Question is, who would take the lead role. I *know* we're all very busy,

mike

At 10:28 AM 3/11/03 -0700, Malcolm Hughes wrote:

I'm with Tom on this. In a way it comes back to a rant of mine to which some of you have already been victim. The general point is that there are two arms of climatology:

neoclimatology - what you do based on instrumental records

and direct, systematic observations in networks - all set in a very Late Holocene/Anthropocene time with hourly to decadal interests.

paleoclimatology - stuff from rocks, etc., where major changes in the Earth system, including its climate, associated with

major changes in boundary conditions, may be detected by examination of one or a handful of paleo records.

Between these two is what we do - "mesoclimatology" - dealing with many of the same phenomena as neoclimatology, using documentary and natural archives to look at phenomena on interannual to millennial time scales. Given relatively small changes in boundary conditions (until the last couple of centuries), mesoclimatology has to work in a way that is very similar to neoclimatology. Most notably, it depends on heavily replicated networks of precisely dated records capable of being either calibrated, or whose relationship to climate may be modeled accurately and precisely.

Because this distinction is not recognized by many (e.g. Sonnechkin, Broecker, Karlen) we see an accumulation of misguided attempts at describing the climate of recent millennia. It would be better to head this off in general, rather than draw attention to a bad paper. After all, as Tom rightly says, we could all nominate really bad papers that have been published in journals of outstanding reputation (although there could well be differences between our lists).

End of rant, Cheers, Malcolm

<x-rich>Dear All,

First, I'd be willing to handle the data and the plotting/mapping. Second, regarding Mike's suggestions, if we use different reference periods for the reconstructions and the models we need to be extremely careful about the differences. Not having seen what this will look like, I suggest that we start with the same instrumental reference period for both (1856-1960). If you are willing to send me your series please send the raw (i.e. unfiltered) series. That way I can treat them all the same. We can then decide how we want to display the results.

Finally, Tom's suggestion of Eos struck me as a great way to get a short, pointed story out to the most people (though I have no feel for the international distribution). My sense (being relatively new to this field compared to everyone else) is that within the neo- and mesoclimate research community there is a (relatively small?) group of people who don't or won't "get it" and there is nothing we can do about them aside from continuing to publish quality work in quality journals (or calling in a Mafia hit). Those (e.g. us) who are engrossed in the issues and are aware of all the literature should be able to distinguish between well done and poor work. Should then the intent of this proposed contribution be to education those who are not directly involved in MWP/LIA issues including those both on the periphery of the issue as well as those outside? If so, then the issue that Phil raised about not letting it get buried is significant and I think Eos is a great way to get people to see it.

Cheers,

Scott

On Wednesday, March 12, 2003, at 10:32 AM, Michael E. Mann wrote:

<excerpt>p.s. The idea of both a representative time-slice spatial plot emphasizing the spatial variability of e.g. the MWP or LIA, and

an EOF analysis of all the records is a great idea. I'd like to suggest a small modification of the latter:

I would suggest we show 2 curves, representing the 1st PC of two different groups, one of empirical reconstructions, the other of model simulations, rather than just one in the time plot.

Group #1 could include:

- 1) Crowley & Lowery
- 2) Mann et al 1999
- 3) Bradley and Jones 1995
- 4) Jones et al, 1998
- 5) Briffa et al 200X? [Keith/Tim to provide their preferred MXD reconstruction]
- 6) Esper et al [yes, no?--one series that differs from the others won't make much of a difference]

I would suggest we scale the resulting PC to the CRU 1856-1960 annual Northern Hemisphere mean instrumental record, which should overlap w/ all of the series, and which pre-dates the MXD decline issue...

Group #2 would include various model simulations using different forcings, and with slightly different sensitivities. This could include 6 or so simulation results:

- 1) 3 series from Crowley (2000) [based on different solar/volcanic reconstructions],
- 2) 2 series from Gerber et al (Bern modeling group result) [based on different assumed sensitivities]
- 1) Bauer et al series (Claussen group EMIC result) [includes 19th/20th century land use changes as a forcing].

I would suggest that the model's 20th century mean is aligned with the 20th century instrumental N.Hem mean for comparison (since this is

when we know the forcings best).

I'd like to nominate Scott R. as the collector of the time series and the performer of the EOF analyses, scaling, and plotting, since Scott already has many of the series and many of the appropriate analysis and plotting tools set up to do this.

We could each send our preferred versions of our respective time series to Scott as an ascii attachment, etc.

thoughts, comments?

thanks,

mike

At 10:08 AM 3/12/2003 -0500, Michael E. Mann wrote:

Thanks Tom,

Either would be good, but Eos is an especially good idea. Both Ellen M-T and Keith Alverson are on the editorial board there, so I think there would be some receptiveness to such a submission.t

I see this as complementary to other pieces that we have written or are currently writing (e.g. a review that Ray, Malcolm, and Henry Diaz are doing for Science on the MWP) and this should proceed entirely independently of that.

If there is group interest in taking this tack, I'd be happy to contact Ellen/Keith about the potential interest in Eos, or I'd be happy to let Tom or Phil to take the lead too...

Comments?

mike

Cc: Tom Crowley <tcrowley@duke.edu>, Phil Jones <p.jones@uea.ac.uk>, Malcolm Hughes <mhughes@ltrr.arizona.edu>, rbradley@geo.umass.edu, k.briffa@uea.ac.uk, t.osborn@uea.ac.uk, mann@virginia.edu

Thanks Scott,

I concur. We may want to try a few different alignment/scaling choices in the end, and

then just vote on which we like the best,

Anxious to here others' thoughts on all of this,

mike

At 10:53 AM 3/12/2003 -0500, Scott Rutherford wrote:

Dear All,

First, I'd be willing to handle the data and the plotting/mapping. Second, regarding Mike's suggestions, if we use different reference periods for the reconstructions and the models we need to be extremely careful about the differences. Not having seen what this will look like, I suggest that we start with the same instrumental reference period for both (1856-1960). If you are willing to send me your series please send the raw (i.e. unfiltered) series. That way I can treat them all the same. We can then decide how we want to display the results.

Finally, Tom's suggestion of Eos struck me as a great way to get a short, pointed story out to the most people (though I have no feel for the international distribution). My sense (being relatively new to this field compared to everyone else) is that within the neo- and mesoclimate research community there is a (relatively small?) group of people who don't or won't "get it" and there is nothing we can do about them aside from continuing to publish quality work in quality journals (or calling in a Mafia hit).

Those (e.g. us) who are engrossed in the issues and are aware of all the literature should be able to distinguish between well done and poor work. Should then the intent of this proposed contribution be to education those who are not directly involved in MWP/LIA issues including those both on the periphery of the issue as well as those outside? If so, then the issue that Phil raised about not letting it get buried is significant and I think Eos is a great way to get people to see it.

Cheers,

Scott

On Wednesday, March 12, 2003, at 10:32 AM, Michael E. Mann wrote:

p.s. The idea of both a representative time-slice spatial plot emphasizing the spatial variability of e.g. the MWP or LIA, and an EOF analysis of all the records is a great idea. I'd like to suggest a small modification of the latter:

I would suggest we show 2 curves, representing the 1st PC of two different groups, one of empirical reconstructions, the other of model simulations, rather than just one in the time plot.

Group #1 could include:

- 1) Crowley & Lowery
- 2) Mann et al 1999
- 3) Bradley and Jones 1995
- 4) Jones et al, 1998
- 5) Briffa et al 200X? [Keith/Tim to provide their preferred MXD reconstruction]
- 6) Esper et al [yes, no?--one series that differs from the others won't make much of a difference]

I would suggest we scale the resulting PC to the CRU 1856-1960 annual Northern

Hemisphere mean instrumental record, which should overlap w/ all of the series, and which pre-dates the MXD decline issue...

Group #2 would include various model simulations using different forcings, and with slightly different sensitivities. This could include 6 or so simulation results:

- 1) 3 series from Crowley (2000) [based on different solar/volcanic reconstructions],
- 2) 2 series from Gerber et al (Bern modeling group result) [based on different assumed sensitivities]

1) Bauer et al series (Claussen group EMIC result) [includes 19th/20th century land use changes as a forcing].

I would suggest that the model's 20th century mean is aligned with the 20th century instrumental N.Hem mean for comparison (since this is when we know the forcings best).

I'd like to nominate Scott R. as the collector of the time series and the performer of the EOF analyses, scaling, and plotting, since Scott already has many of the series and many of the appropriate analysis and plotting tools set up to do this.

We could each send our preferred versions of our respective time series to Scott as an ascii attachment, etc.

thoughts, comments?

thanks,

mike

At 10:08 AM 3/12/2003 -0500, Michael E. Mann wrote:

Thanks Tom,

Either would be good, but Eos is an especially good idea. Both Ellen M-T and Keith Alverson are on the editorial board there, so I think there would be some receptiveness to such a submission.t

I see this as complementary to other pieces that we have written or are currently writing (e.g. a review that Ray, Malcolm, and Henry Diaz are doing for Science on the MWP) and this should proceed entirely independently of that.

If there is group interest in taking this tack, I'd be happy to contact Ellen/Keith about the potential interest in Eos, or I'd be happy to let Tom or Phil to take the lead too...

Comments?

mike

At 09:15 AM 3/12/2003 -0500, Tom Crowley wrote:

Phil et al,

I suggest either BAMS or Eos - the latter would probably be better because it is shorter, quicker, has a wide distribution, and all the points that need to be made have been made before.

rather than dwelling on Soon and Baliunas I think the message should be pointedly made against all of the standard claptrap being dredged up.

I suggest two figures- one on time series and another showing the spatial array of temperatures at one point in the Middle Ages. I produced a few of those for the Ambio paper but already have one ready for the Greenland settlement period 965-995 showing the regional nature of the warmth in that figure. we could add a few new sites to it, but if people think otherwise we could of course go in some other direction.

rather than getting into the delicate question of which paleo reconstruction to use I suggest that we show a time series that is an eof of the different reconstructions - one that emphasizes the commonality of the message.

Tom

Dear All,

I agree with all the points being made and the multi-authored article would be a good idea, but how do we go about not letting it get buried somewhere. Can we not address the misconceptions by finally coming up with definitive dates for the LIA and MWP and redefining what we think the terms really mean? With all of us and more on the paper, it should carry a lot of weight. In a way we will be setting the agenda for what should be being done over the next few years.

We do want a reputable journal but is The Holocene the right vehicle. It is probably the best of its class of journals out there. Mike and I were asked to write an article for the EGS journal of Surveys of Geophysics. You've not heard of this - few have, so we declined. However, it got me thinking that we could try for Reviews of Geophysics. Need to contact the editorial board to see if this might be possible. Just a thought, but it certainly has a high profile.

What we want to write is NOT the scholarly review a la Jean Grove (bless her soul) that just reviews but doesn't come to anything firm. We want a critical review that enables agendas to be set. Ray's recent multi-authored piece goes a lot of the way so we need to build on this.

Cheers

Phil

At 12:55 11/03/03 -0500, Michael E. Mann wrote:

HI Malcolm,

Thanks for the feedback--I largely concur. I do, though, think there is a particular problem with "Climate Research". This is where my colleague Pat Michaels now publishes exclusively, and his two closest colleagues are on the editorial board and review editor board. So I promise you, we'll see more of this there, and I personally think there *is* a bigger problem with the "messenger" in this case...

But the Soon and Baliunas paper is its own, separate issue too. I too like Tom's latter idea, of a more hefty multi-authored piece in an appropriate journal (Paleoceanography? Holocene?) that seeks to correct a number of misconceptions out there, perhaps using Baliunas and Soon as a case study ('poster child?'), but taking on a slightly greater territory too.

Question is, who would take the lead role. I *know* we're all very busy, mike

At 10:28 AM 3/11/03 -0700, Malcolm Hughes wrote:

I'm with Tom on this. In a way it comes back to a rant of mine to which some of you have already been victim. The general point is that there are two arms of climatology: neoclimatology - what you do based on instrumental records and direct, systematic observations in networks - all set in a very Late Holocene/Anthropocene time with hourly to decadal interests. paleoclimatology - stuff from rocks, etc., where major changes

in the Earth system, including its climate, associated with major changes in boundary conditions, may be detected by examination of one or a handful of paleo records.

Between these two is what we do - "mesoclimatology" - dealing with many of the same phenomena as neoclimatology, using documentary and natural archives to look at phenomena on interannual to millennial time scales. Given relatively small changes in boundary conditions (until the last couple of centuries), mesoclimatology has to work in a way that is very similar to neoclimatology. Most notably, it depends on heavily replicated networks of precisely dated records capable of being either calibrated, or whose relationship to climate may be modeled accurately and precisely.

Because this distinction is not recognized by many (e.g. Sonnechkin, Broecker, Karlen) we see an accumulation of misguided attempts at describing the climate of recent millennia. It would be better to head this off in general, rather than draw attention to a bad paper. After all, as Tom rightly says, we could all nominate really bad papers that have been published in journals of outstanding reputation (although there could well be differences between our lists).

End of rant, Cheers, Malcolm

Dear Tim,

Thanks for your rapid replies and your help. This is all very useful.

Well, lets see what this gives...

There are some notable differences just between our relative comparisons of the different series which must have something to do with the relative scaling and aligning of the series. The position of Crowley and Lowery, in particular, is quite inconsistent between our respective comparisons. When we scale the various series to the full N. Hem instrumental annual mean CRU record 1856-1980, we get a a very different relative ordering of the different series, as shown in the attached figure from my Science perspective piece from last year

This should not, however, influence the EOF decomposition if all series are zero-mean and standardized prior to the EOF analysis, but the scaling and alignment of the result, in the end, will be sensitive to all of these various issues.

So, in short, lets see what we get, and then discuss any similarities/differences w/ your result, then make a decision as to what to show in the Eos piece. I'm sure we can come up w/ something we're all happy with...

Please do send us your & Keith's preferred version of the MXD reconstruction--we'll collect the others from the individual sources (most we already have, I think)...

mike

At 16:29 12/03/03, Michael E. Mann wrote:

but there are many variables here [not the least of which is the choice of scaling the series to an extratropical summer mean, which as we have argued before, we don't think is appropriate for a full N. Hem mean because of changes in meridional temperature gradient over time, and the choice of calibration period--I wonder if 1856-1960 or 1856-1980 gives a more stable result).

True, but as I indicated I have tried alternatives. The attached is what I get with annual mean temperature as the target series - still taken only from land >20N though [but I have extracted that domain from your spatial reconstructions to produce the time series that I used for "Mann et al." - which should make it reasonably appropriate back to 1400 at least]. I have also tried different calibration periods (including not calibrating against instrumental data at all!). All give qualitatively similar results - see attached .pdf and compare with the first one I sent.

The point is, that (I believe) the approach will introduce a *new* result and while that is interesting it wouldn't be appropriate for a short EOS piece - and having found this out, I was trying to save you the effort.

But, on reflection, it would be good if you went ahead and did this anyway, because the results might well be useful to publish in another paper, even if they weren't deemed suitable for the EOS piece.

I could provide the 7 series that I have used, but would prefer that you got them from

the original sources to ensure that you have the most up-to-date/correct versions.

Cheers

Tim

<x-flowed>

This is an excellent idea, Mike, IN PRINCIPLE at least. In practise, however, it raises some interesting results (as I have found when attempting this myself) that may be difficult to avoid getting bogged down with discussing.

The attached .pdf figure shows an example of what I have produced (NB. please don't circulate this further, as it is from work that is currently being finished off - however, I'm happy to use it here to illustrate my point).

I took 7 reconstructions and re-calibrated them over a common period and against an observed target series (in this case, land-only, Apr-Sep, >20N - BUT I GET SIMILAR RESULTS WITH OTHER CHOICES, and this re-calibration stage is not critical). You will have seen figures similar to this in stuff Keith and I have published. See the coloured lines in the attached figure.

In this example I then simply took an unweighted average of the calibrated series, but the weighted average obtained via an EOF approach can give similar results. The average is shown by the thin black line (I've ignored the potential problems of series covering different periods). This was all done with raw, unsmoothed data, even though 30-yr smoothed curves are plotted in the figure.

The thick black line is what I get when I re-calibrate the average record against my target observed series. **THIS IS THE IMPORTANT BIT.** The *re-calibrated* mean of the reconstructions is nowhere near the mean of the reconstructions. It has enhanced variability, because averaging the reconstructions results in a redder time series (there is less common variance between the reconstructions at the higher frequencies compared with the lower frequencies, so the former averages out to leave a smoother curve) and the re-calibration is then more of a case of fitting a trend (over my calibration period 1881-1960) to the observed trend. This results in enhanced variability, but also enhanced uncertainty (not shown here) due to fewer effective degrees of freedom during calibration.

Obviously there are questions about observed target series, which series to include/exclude etc., but the same issue will arise regardless: the

analysis will not likely lie near to the middle of the cloud of published series and explaining the reasons behind this etc. will obscure the message of a short EOS piece.

It is, of course, interesting - not least for the comparison with borehole-based estimates - but that is for a separate paper, I think.

My suggestion would be to stick with one of these options:

- (i) a single example reconstruction;
- (ii) a plot of a cloud of reconstructions;
- (iii) a plot of the "envelope" containing the cloud of reconstructions (perhaps also the envelope would encompass their uncertainty estimates), but without showing the individual reconstruction best guesses.

How many votes for each?

Cheers

Tim

Daer Armin,

I would like to confirm that RIVM is strongly committed to make a
substantial contribution to the AMS proposal, as was clear from our
active
involvement in the discussions so far (except the Paris meeting where we
unfortunately could not send a representative). We have been in touch
with
several other partners in developing ideas for the workpackage, but in
view
of the high pressure under which the proposal is being put together,
communication is not always easy. I therefore include a list of elements
we
would like to contribute to the respective parts of the proposal:.

WP1. Scenarios: involved with proposal Brian O'Neill (contact:
Detlef
van Vuuren). Important issues: delineation with scenarios in other
workpackages - no response so far.

WP 3.1. Possible contribution, depends on connection with WP1
3.3. Primarily through cooperation with Un.Utrecht - proposal sent
to
Wokaun but no response. Possible to add global context with IMAGE/TIMER
and
add non-energy emssion reductions not covered in original proposal by
Wokaun

3. 4. and 3.5: as for 3.3

WP 4.1. Suggested role for multi-gas stabilization profiles, burden sharing regimes and EU action with IMAGE-FAIR combination (building on work

we have done with other partners for the European Commission). Current proposal by Haxeltine, Leemans and Adger has 100% focus on impacts and adaptation and should be broadened. We are ready to contribute

4.2. Now contains the regimes that should go under 4.1

4.6. Involved actively: see proposal Olsson&Metz that went to John Schellhuber

WP 5.4. Strong interest, but no response from coordinator (C. Jaeger) and

WP coordinator Hasselmann refers back to CJ (!). We will put together proposal with Tyndall towards development of CIAS model.

Best regards,

Bert Metz

Press release from Earth Government and April Newsletter
FOR IMMEDIATE RELEASE

This Press release from Earth Government is found at
[1]<http://members.shaw.ca/earthgov/HNewsPR05.htm>

Formation of Earth Government for the good of all

March 27th, 2003

To all Peoples of the Earth,

Earth has long been waiting for a truly global governing body based on universal values, human rights, global concepts and democracy. Earth Government might as well be created now, there is no longer any reason to wait. We are the Earth Community, and we will form the Earth Government. Earth management is a priority and is a duty by every responsible person. A democratically elected Earth Government will now be formed, and we want you to reflect on future effects of such an event on the history of humanity. Certainly one will expect extraordinary changes: a reorganizing of human activities all over the planet; participation by all societies on the planet in solving local and global problems; new alliances forming; north meeting with south (eradication of poverty will be the price to pay to get votes from the south) in order to gather more votes within the newly created Earth Government to satisfy power struggles between European, Asian and Western countries; adoption of democratic principles, human and Earth rights, global concepts, and universal values by every human being; expansion of consciousness; gathering and coordinating of forces to resolve social and political problems in a peaceful way (no more conflicts or wars); gathering and coordinating of forces (technologies, scientific research, exploration work, human resources, etc.) to resolve global problems such as global climate, environment, availability of resources, poverty, employment, etc. Thousands more changes!

Let your heart and mind reflect on 'the good' of a democratically elected Earth Government. Everyone is part of Earth Community by birth and therefore everyone has a right to vote. Everyone should be given a chance to vote. Decisions will be made democratically.

Earth Government is proposing that:

- a) different nations may require different political systems at different times
- b) a democratic system is not a "must have it" to be a responsible member nation of the Earth Government
- c) all democracies are to be upgraded, or improved upon, to be a responsible member nation of the Earth Government. The Scale of Human and Earth Rights and the Charter of the Earth

Government are the newly added requirements to all democratic systems of the world.

In today's Earth Government it is important for our survival to cooperate globally on several aspects such as peace, security, pollution in the air, water and land, drug trade, shelving the war industry, keeping the world healthy, enforcing global justice for all, eradicating poverty worldwide, replacing the Universal Declaration of Human Rights by the Scale of Human and Earth Rights, and entrenching the Charter of Earth Government as a way of life for the good of all.

Earth needs urgently a world system of governance. The United Nations fail to satisfy the needs of the people of the 21st Century. It has never improved upon the old ways and thinking of the middle of the 20th Century. Its voting system no longer satisfy the 6.157 billion people on Earth. The challenges are different and require a world organization up for dealing with the needs of all these people.

During the past several years, the Earth Government has been pleading the United Nations leaders to make changes in the UN organizational structure and ways of doing things. There has been an urgent need for fundamental changes in the United Nations organization. The decision of the United States Government to invade the Middle East nations and Afghanistan has shown to be a result of this incapacity for changes on the part of the United Nations. A lack of leadership at the United Nations is a major threat to the security of the world. The world wants a true democratic world organization. The UN is not!

The most fundamental requirement of a world organization is a democratic system of voting. Democracy must be a priority. The right that the greatest number of people has by virtue of its number (50% plus one) is a human right. It should be respected. The actual UN system of voting is undemocratic, unfair and noone likes it. It does not work! Earth Government has proposed a voting system based on democracy.

Of the 190 Member States of the United Nations, it takes only one of the five permanent members to overthrow any decision or proposal during a meeting. This means 1/189 or 0.5% of the membership is more powerful than the remaining 99.5%. If that is not a dictatorship, what is it? It does not say much about democracy at the UN. More like a dictatorship of the five permanent members. In the Preamble of the Charter of the United Nations, it says "WE THE PEOPLES OF THE UNITED NATIONS " but in fact it should say "WE THE FIVE PERMANENT MEMBERS".

The voting system for Earth Government is very simple and practical. One representative per million people. If all countries in the world had decided now to participate with this process we would have today 6,114 elected representatives to form Earth Government. They would form the Legislative body of Earth Government. They could actually all stay home to govern or from some place in their communities. Today communications are more than good enough to allow voting and discussing issues, etc. through the Internet and video conferencing. That would cut cost of governing down to a minimum, at least administrative costs. The Executive body would also govern in this way to cut cost down to a minimum. Ministers can administer their Ministries from where they live if they wish to. There will be a place for the Headquarters. We will show that it costs very little to administer Earth Government, and that we can achieve immense results. There is no limit to the good the Earth Government can achieve in the world. Think! What can do a unified 6.114 billion

people determined to make things work to keep Earth healthy?

For the first time in human history, and the first time this millennium, humanity has proposed a benchmark:

- * formation of Earth Government
- * formation of global ministries in all important aspects of our lives
- * the Scale of Human and Earth Rights as a replacement to the Universal Declaration of Human Rights
- * an evolved Democracy based on the Scale of Human and Earth Rights and the Charter of the Earth Government
- * a central organization for Earth management, the restoration of the planet and Earth governance: the Global Community Assessment Centre (GCAC)
- * the Earth Court of Justice to deal with all aspects of the Governance and Mangement of the Earth
- * a new impetus given to the way of doing business and trade
- * more new, diversified (geographical, economical, political, social, business, religious) symbiotical relationships between nations, communities, businesses, for the good and well-being of all
- * the event and formation of the human family and the Soul of Humanity
- * proposal to reform the United Nations, the World Trade Organization, the World Bank, the IMF, NAFTA, FTAA, and to centralize them under Earth Government, and these organizations will be asked to pay a global tax to be administered by Earth Government
- * the Peace Movement of the Earth Government and shelving of the war industry from humanity
- * a global regulatory framework for capitals and corporations that emphasizes global corporate ethics, corporate social responsibility, protection of human and Earth rights, the environment, community and family aspects, safe working conditions, fair wages and sustainable consumption aspects
- * the ruling by the Earth Court of Justice of the abolishment of the debt of the poor or developing nations as it is really a form of global tax to be paid annually by the rich or industrialized nations to the developing nations
- * establishing freshwater and clean air as primordial human rights

The political system of an individual country does not have to be a democracy. Political rights of a country belong to that country alone. Democracy is not to be enforced by anyone and to anyone or to any community. Every community can and should choose the political system of their choice with the understanding of the importance of such a right on the Scale of Human and Earth Rights. On the other hand, representatives to Earth Government must be elected democratically in every part of the world. An individual country may have any political system at home but the government of that country will have to ensure (and allow verification by Earth Government) that representatives to Earth Government have been elected democratically. This way, every person in the world can claim the birth right of electing a democratic government to manage Earth: the rights to vote and elect representatives to form the Earth Government.

In order to elect representatives to Earth Government it is proposed the following:

A. Each individual government in the world will administer the election of representatives to Earth Government with an NGO and/or members of Earth Government be allowed to verify all aspects of the process to the satisfaction of all parties involved.

B. Representatives be elected every five years to form a new Earth Government.

C. It is proposed here that there will be one elected representative per 1,000,000 people. A population of 100 million people will elect 100 representatives. This process will create a feeling of belonging and participating to the affairs of the Earth Community and Earth Government.

D. A typical community of a million people does not have to be bounded by a geographical or political border. It can be a million people living in many different locations all over the world. The Global Community is thus more fluid and dynamic. We need to let go the archaic ways of seeing a community as the street where I live and contained by a border. Many conflicts and wars will be avoided by seeing ourselves as people with a heart, a mind and a Soul, and as part of a community with the same.

E. Earth population is now 6.114 billion people. If all representatives had been elected this year there would be 6,114 representatives to form Earth Government. They would be the Legislative elected body of Earth Government. They would participate in some ways in choosing the Executive and Judiciary bodies of Earth Government.

Humanity has now a Vision of the Earth in the years to come and a sense of direction.

May the DIVINE WILL come into our lives and show us the way.

May our higher purpose in life bring us closer to the Soul of Humanity and God.

Subject: Re: Re: Holclim follow up
Date: Mon 7 Apr 2003 16:04

Dear Keith.

I had a chat with Dominique Reynaud on this matter today here in Nice. His impression is the same, but added that he thinks Brussels would insist on a NoE rather than an IP. If we wish to have an IP it needs lobbying it seems. He told about the meeting in Brussels in June. I am not invited as far as I can tell. Dominique mentioned that Nick Shackleton would be there and I will talk with him. The key thing would be to sort out what the most exciting science our community can offer when we integrate the communities.

In terms of meetings it seems to depend a little of what comes out of the June meeting in Brussels.

Cheers

Eystein

Subject: My turn
Date: Wed, 23 Apr 2003 23:53:38 -0600

Dear friends,

[Apologies to those I have missed who have been part of this email exchange -- although they may be glad to have been missed]

I think Barrie Pittock has the right idea -- although there are some unique things about this situation. Barrie says

- (1) There are lots of bad papers out there
- (2) The best response is probably to write a 'rebuttal'

to which I add

- (3) A published rebuttal will help IPCC authors in the 4AR.

Let me give you an example. There was a paper a few years ago by Legates and Davis in GRL (vol. 24, pp. 2319-1222, 1997) that was nothing more than a direct

and pointed criticism of some work by Santer and me -- yet neither of us was asked to review the paper. We complained, and GRL admitted it was poor judgment on the part of the editor. Eventually (> 2 years later) we wrote a response (GRL 27, 2973-2976, 2000). However, our response was more than just a rebuttal, it was an attempt to clarify some issues on detection. In doing things this way we tried to make it clear that the original Legates/Davis paper was an example of bad science (more bluntly, either sophomoric ignorance or deliberate misrepresentation).

Any rebuttal must point out very clearly the flaws in the original

paper. If some new science (or explanations) can be added -- as we did in the above example -- then this is an advantage.

There is some personal judgment involved in deciding whether to rebut. Correcting bad science is the first concern. Responding to unfair personal criticisms is next. Third is the possible misrepresentation of the results by persons with ideological or political agendas. On the basis of these I think the Baliunas paper should be rebutted by persons with appropriate expertise. Names like Mann, Crowley, Briffa, Bradley, Jones, Hughes come to mind. Are these people willing to spend time on this?

There are two other examples that I know of where I will probably be involved in writing a response.

The first is a paper by Douglass and Clader in GRL (vol. 29, no. 16, 10.1029/2002GL015345, 2002). I refereed a virtually identical paper for J. Climate, recommending rejection. All the other referees recommended rejection too. The paper is truly appalling -- but somehow it must have been poorly reviewed by GRL and slipped through the net. I have no reason to believe that this was anything more than chance. Nevertheless, my judgment is that the science is so bad that a response is necessary.

The second is the paper by Michaels et al. that was in Climate Research (vol. 23, pp. 109, 2002). Danny Harvey and I refereed this and said it should be rejected. We questioned the editor (deFreitas again!) and he responded saying

The MS was reviewed initially by five referees. ... The other three referees, all reputable atmospheric scientists, agreed it should be published subject to minor revision. Even then I used a sixth person to help me decide. I took his advice and that of the three other referees and sent the MS back for revision. It was later accepted for publication. The refereeing process was more rigorous than usual.

On the surface this looks to be above board -- although, as referees who advised rejection it is clear that Danny and I should have been kept in the loop and seen how our criticisms were responded to.

It is possible that Danny and I might write a response to this paper -- deFreitas has offered us this possibility.

This second case gets to the crux of the matter. I suspect that deFreitas deliberately chose other referees who are members of the skeptics camp. I also suspect that he has done this on other occasions. How to deal with this is unclear, since there are a number of individuals with bona fide scientific credentials who could be used by an unscrupulous editor to ensure that 'anti-greenhouse' science can get

through the peer review process (Legates, Balling, Lindzen, Baliunas, Soon, and so on).

The peer review process is being abused, but proving this would be difficult.

The best response is, I strongly believe, to rebut the bad science that does get through.

Jim Salinger raises the more personal issue of deFreitas. He is clearly giving good science a bad name, but I do not think a barrage of ad hominem attacks or letters is the best way to counter this.

If Jim wishes to write a letter with multiple authors, I may be willing to sign it, but I would not write such a letter myself.

In this case, deFreitas is such a poor scientist that he may simply disappear. I saw some work from his PhD, and it was awful (Pat Michaels' PhD is at the same level).

Best wishes to all,
Tom.

Tim,

I know about what Matthews has done. He did so without contacting Sarah or me. He uses a statistical emulation method that can never account for the full range of uncertainties. I would not trust it outside the calibration zone -- so I doubt that it can work well for (e.g.) stabilization cases. As far as I know it has not been peer reviewed. Furthermore, unless he has illegally got hold of the TAR version of the model, what he has done can only be an emulation of the SAR version.

Personally, I regard this as junk science (i.e., not science at all).

Matthews is doing the community a considerable disservice.

Tom.

PS Re CR, I do not know the best way to handle the specifics of the editing. Hans von Storch is partly to blame -- he encourages the publication of crap science 'in order to stimulate debate'. One approach is to go direct to the publishers and point out the fact that their journal is perceived as being a medium for disseminating misinformation under the guise of refereed work. I use the word 'perceived' here, since whether it is true or not is not what the publishers care about -- it is how the journal is seen by the community that counts.

I think we could get a large group of highly credentialed scientists to sign such a letter -- 50+ people.

Note that I am copying this view only to Mike Hulme and Phil Jones. Mike's idea to get editorial board members to resign will probably not work -- must get rid of von Storch too, otherwise holes will eventually fill up with people like Legates, Balling, Lindzen, Michaels, Singer, etc. I have heard that the publishers are not happy with von Storch, so the above approach might remove that hurdle too.

<x-flowed>
HI Mark,

Thanks for your comments, and sorry to any of you who don't wish to receive these correspondances...

Indeed, I have provided David Halpern with a written set of comments on the offending paper(s) for internal use, so that he was armed w/ specifics as he confronts the issue within OSTP. He may have gotten additional comments from other individuals as well--I'm not sure. I believe that the matter is in good hands with Dave, but we have to wait and see what happens. In any case, I'd be happy to provide my comments to anyone who is interested.

I think that a response to "Climate Research" is not a good idea. Phil and I discussed this, and agreed that it would be largely unread, and would tend to legitimize a paper which many of us don't view as having passed peer review in a legitimate manner. On the other hand, the in prep. review articles by Jones and Mann (Rev. Geophys.), and Bradley/Hughes/Diaz (Science) should go along way towards clarification of the issues (and, at least tangentially, refutation of the worst of the claims of Baliunas and co). Both should be good resources for the FAR as well...

cheers,

mike

p.s. note the corrections to some of the emails in the original distribution list.

Dear friends and colleagues

This will be the last from me for the moment and I believe we are all arriving at a consensus voiced by Tom, Barrie, Neville et al., from excellent discussions.

Firstly both Danny and Tom have complained to de Freitas about his editorial decision, which does not uphold the principles of good science. Tom has shared the response. I would be curious to find out who the other four cited are - but a rebuttal would be excellent.

Ignoring bad science eventually reinforces the apparent 'truth' of that bad science in the public mind, if it is not corrected. As importantly, the 'bad science' published by CR is used by the sceptics' lobbies to 'prove' that there is no need for concern over climate change. Since the IPCC makes it quite clear that there are substantial grounds for concern about climate change, is it not partially the responsibility of climate science to make sure only satisfactorily peer-reviewed science appears in scientific publications? - and to refute any inadequately reviewed and wrong articles that do make their way through the peer review process?

I can understand the weariness which the ongoing sceptics' onslaught would induce in anyone, scientist or not. But that's no excuse for ignoring bad science. It won't go away, and the more we ignore it the more traction it will gain in the minds of the general public, and the UNFCCC negotiators. If science doesn't uphold the purity of science, who will?

We Australasians (including Tom as an ex pat) have suggested

some courses of action. Over to you now in the north to assess the success of your initiatives, the various discussions and suggestions and arrive on a path ahead. I am happy to be part of it.

Warm wishes to all

Jim

Thanks Ed

Can I just say that I am not in the MBH camp - if that be characterized by an unshakable "belief" one way or the other, regarding the absolute magnitude of the global MWP. I certainly believe the "medieval" period was warmer than the 18th century - the equivalence of the warmth in the post 1900 period, and the post 1980s, compared to the circa Medieval times is very much still an area for much better resolution. I think that the geographic / seasonal biases and dating/response time issues still cloud the picture of when and how warm the Medieval period was. On present evidence, even with such uncertainties I would still come out favouring the "likely unprecedented recent warmth" opinion - but our motivation is to further explore the degree of certainty in this belief - based on the realistic interpretation of available data. Point re Jan well taken and I will inform him
At 07:59 AM 4/29/03 -0400, you wrote:

Hi Keith,

I will start out by sending you the chronologies that I sent Bradley, i.e. all but Mongolia. If you can talk Gordon out of the latter, you'll be the first from outside this lab. The chronologies are in tabbed column format and Tucson index format. The latter have sample size included. It doesn't take a rocket scientist (or even Bradley after I warned him about small sample size problems) to realize that some of the chronologies are down to only 1 series in their earliest parts. Perhaps I should have truncated them before using them, but I just took what Jan gave me and worked with the chronologies as best I could. My suspicion is that most of the pre-1200 divergence is due to low replication and a reduced number of available chronologies. I should also say that the column data have had their means normalized to approximately 1.0, which is not the case for the chronologies straight out of ARSTAN. That is because the site-level RCS-detrended data were simply averaged to produce these chronologies, without concern for their long-term means. Hence the "RAW" tag at the end of each line of indices. Bradley still regards the MWP as "mysterious" and "very incoherent" (his latest pronouncement to me) based on the available data. Of course he and other members of the MBH camp have a fundamental dislike for the very concept of the MWP, so I tend to view their evaluations as starting out from a somewhat biased perspective, i.e. the cup is not only "half-empty"; it is demonstrably "broken". I come more from the "cup half-full" camp when it comes to the MWP, maybe yes, maybe no, but it is too early to say what it is. Being a natural skeptic, I guess you might lean more towards the MBH camp, which is fine as long as one is honest and open about evaluating the evidence (I have my doubts about the MBH camp). We can always politely(?) disagree given the same admittedly equivocal evidence.

I should say that Jan should at least be made aware of this reanalysis of his data. Admittedly, all of the Schweingruber data are in the public domain I believe, so that should not be an issue with those data. I just don't want to get into an open critique of the Esper data because it would just add fuel to the MBH attack squad. They tend to work in their own somewhat agenda-filled ways. We should also work on this stuff on our own, but I do not think that we have an agenda per se, other than trying to objectively understand what is going on.

Cheers,
Ed

Ed

thanks for this - and it is intriguing , not least because of the degree of coherence in these series between 1200 and 1900 - more than can be accounted for by either replication of data between the series (of which there is still some) or artifact of the standardisation method (with the use of RCS curves which are possibly inappropriate for all the data to which each is applied) . Having then got some not insubstantial confidence in the likelihood of a real temperature signal in this period - the question of why the extreme divergence in the series pre-1200 and post 1900? A real geographic difference in the forcing , replication and standardisation problems? - both are likely. We would like the raw cores for each site: the RCS indices upon which you base the chronologies ; the site chronologies (which I think you sent to Ray?). At first we will simply plot the site chronologies , correlate each with local climate and come back to you again. We will also plot each "set" of indices and compare site RCS curves and reconsider the validity of the classification into linear and non-linear growth patterns. I know you have done all this but we need to get a feel for these data and do some comparisons with my early produce ring-width RCS chronologies for certain sites and compare the TRW series with the same site MXD chronologies - all a bit suck and see at first. I am talking with Tim later today about the review idea and I will email/phone before 16.00 my time today.

Thanks

Keith

Hi Keith,

Here is the new Esper plot with three different forms of regionalization: linear vs. nonlinear (as in the original paper), north vs. south as defined in the legend, and east vs. west (i.e. eastern hemisphere vs. western hemisphere). All of the series have been smoothed with a 50-yr spline after first averaging the annual values. The number of cores/chronologies are given in the legend in parentheses. Not surprisingly, the north and south chronologies deviate most in the post-1950 period. Before 1950 and back to about 1200 the series are remarkably similar (to me anyway). Prior to 1200 there is more chaos, perhaps because the number of chronologies have declined along with the within-chronology replication. However, there is still some evidence for spatially

coherent above-average growth. I showed this plot at the Duke meeting. Karl Taylor actually told me that he thought it looked fairly convincing, i.e. that the low-frequency structure in the Esper series was not an artefact of the RCS method.

Cheers,
Ed

Hi Keith,

No problem, I know how hectic the past couple months have been for you, so no apologies necessary whatsoever!

Call me old fashioned, but I still tend to prefer the "blind" reviewer convention, so I'd prefer to remain anonymous unless you think that revealing my identity would be help in any particular way.

I agree w/ your take on this--a journal like GRL is probably more appropriate, or even "Climatic Change" because a number of similar papers have been published there in the past (by folks like Nychka, Bloomfield, and others). I'm not sure if Steve Schneider is sick and tired of those papers though...

Please don't hesitate to let me know if I can be of any additional help w/ this.

Looking forward to seeing you one of these days,
mike

in hassling another reviewer , I realised that I did not thank you properly for the review you did of the manuscript by Gil-Alana (fractionally integrated techniques used to show increased persistence in global temperature record in 20th century). So this is by way of thanks and to ask whether you wish me to reveal your name to the reviewer (considering you make some very helpful suggestions for further analysis)? I would otherwise assume no. As it happens I can not get a response from the other reviewer - but rather than prolong the wait for the submitter , I am tempted (on the basis of my reading also) to just send your comments and reject the manuscript as it is - I suppose they could resubmit a major rework following your suggestions - but I tend to the opinion that it would be better suited to another journal anyway - GRL comes to mind. What do you think

Cheers

Keith

just back from really sunny Austria and very pleasant south of France. Have talked at length with Jan and he says it is fine to send the raw and detrended cores series (segmented for each site if possible). Do you also have a convenient Table with the Lats and Longs you used to plot the sites map? This would mean I don't have to look them all up. I will phone to report on our discussions and ask several things that arose from these. Just have to do essential other stuff first - so probably tuesday afternoon (my time) Do you have that review yet?

love and kisses

Keith

Lennart has managed to confuse me with his latest message. At one point he mentioned that you and I would do a joint overview paper . Now he suggests we choose 5-10 co-authors but also refers to "other people in our section" who he has apparently already informed , need "to consult with you (ie us) as required" (my emphasis).

As for my opinion of the theme or content of our section , I suggest it be "quantifying Natural and Anthropogenic influences on the course of Global climate during recent millennia" or some such . This allows for the review , redefinition of Global climate history (Southern as well as Northern , and moisture as well as Temperature). Importantly , it also incorporates the issue of forcing history(ies) and work quantifying the influence of these histories - using simple empirical techniques or using them in conjunction with models of different complexity to attribute causes of this change.

I am happy to go with the "usual suspects" in the overview paper , but would be happy if we considered others who are also running controlled model/data comparisons (examples are Von Storch , Simon Tett , Caspar Ammann). We need first to clarify whether we will present one large , multi-author presentation/paper or whether it is just me and you and the others divided into other papers/presentations/posters. Should we copy this message to Lennart or contact him directly with specific questions?

Keith

At 09:49 PM 5/18/03 -0400, you wrote:

Hi Keith,

I hope all is well.

Apparently, we're supposed to choose 5-10 additional "co-authors"? I guess the obvious ones would be Phil, Tim, Ray, Malcolm, perhaps Ed Cook, Scott Rutherford,...any other suggestions?

As I understand it, the co-authors would be invited to attend and present in the poster session; I assume they are listed separately from you and I who will jointly present the oral overview. As for the theme, I'm assuming "climate changes of the past couple/few millennia" or something like that. As we have 45 minutes total between the two of us, I would suggest we each take about 20 minutes, and then we'll have 5 minutes left for questions.

Any suggestions, thoughts would be greatly appreciated.

thanks,

mike

--

Dear Dr. Mann,

Dear Dr. Briffa,

The preparation of the Clivar conference is progressing well and all invited speakers have now agreed (See attached draft program). As I have informed you previously Journal of Climate will have a special issue devoted to the Conference and I expect you would be willing to prepare a paper to be ready at the time of the conference. I have made arrangements with the chief editor to make a flexible interpretation of the content of the papers so to agree with the objective of the conference and the draft program.

We would now like you to come up with a suitable theme for your presentation at the conference as well a list of names which you have selected as co-authors. As we anticipate a broad and forward-looking contribution I believe some 5-10 people seems appropriate. It was our intention that the first person listed should be the lead author but you can arrange this otherwise if you prefer to do so. I have informed the other speakers in your section to consult with you as required.

For the conference I expect a rather wide audience in addition to a broad scientific community including representatives from different agencies such as the meteorological services, as well as media representatives. For the media we intend to provide a special set of information. In view of the societal importance of the CLIVAR program and the considerable progress in extended range forecasts and climate change assessment and prediction I believe there will be an excellent opportunity to bring the scientific progress and associated applications of CLIVAR to the participants of the conference. It would be very helpful if you could let me know the status of your arrangements not later than June 15. If you see any particular difficulties please let me know as soon as possible.

As you can see from the attached program each part of the conference will have poster sessions. The poster sessions will be an important part of the conference and I anticipate that some of your co-authors will prepare such posters. We also plan to have the poster contents on a CD ROM prior to the conference.

The practical planning of the conference as a whole is proceeding well. The arrangements in Baltimore are quite excellent with the nearby Baltimore inner harbor as a particular attractive focal point. There are all reasons that the conference will be a success both scientifically and socially. See further the Clivar Conference website:

[1] <http://www.clivar2004.org>.

We are presently exploring the possibilities for financial support of selected participants. However, any support you may manage to obtain from national funds would be most helpful.

With my very best regards

Lennart Bengtsson

Mike and Tom and others

My silence to do with the specific issue of the Soon and Baliunas conveys general strong agreement with all the general remarks (and restatement of many in various forms) by Tom Crowley, Mike Mann, Neville Nichols and now Tom Wigley regarding the scientific value of the paper and its obvious methodological flaws.

I have to say that I tended towards the "who cares" camp , in as much as those who are concerned about the science should see through it anyway . I also admit to thinking that some of you seem a little paranoid (especially in the implication that Climate Research is a pro sceptic journal) but I am changing my mind regarding the way the "meaning" of the BS paper is being presented to the wider public - in response to some very poor recent reporting in the British press and several requests from the US that indicate that those of you who work there can not simply rely on the weight of good science eventually showing through as regards the public perception . As Tom W. states , there are uncertainties and "difficulties" with our current knowledge of Hemispheric temperature histories and valid criticisms or shortcomings in much of our work. This is the nature of the beast - and I have been loathe to become embroiled in polarised debates that force too simplistic a presentation of the state of the art or "consensus view". Having read Tom W's and Mike's latest statements I now agree about the need to make some public comment on BS . (I too have given my personal view of the work to David Appell who I assume is writing a balanced view of this paper for Scientific American). I see little need to get involved in a over detailed critic of all the points in the paper , because I am not sure what audience would benefit from it, but the points made by those I listed above could usefully be fashioned into a simple letter to Climate Research, signed by those who wish. This would then go on record as a simple statement of refutation of the method employed and corresponding limitation of the work for informing the "global warming " debate . This could be quickly citable when talking to the media.

The one additional point I would make that seems to have been overlooked in the discussions up to now , is the invalidity of assuming that the existence of a global Medieval Warm period , even if shown to be as warm as the current climate , somehow negates the possibility of enhanced greenhouse warming. The business of constructing a reliable climate history is only one part of establishing the relative roles of natural and anthropogenic forcings, now and in the future. Without reference to the roles of natural forcings in recent and past times , comparisons with other periods are of very limited value anyway. So I agree with Tom and Mike that something needs to go "on record" . The various papers apparently in production, regardless of their individual emphasis or approaches, will find their way in to the literature and the next IPCC can sift and present their message(s) as it wishes., but in the meantime , why not a simple statement of the shortcomings of the BS paper as they have been listed in these messages and why not in Climate Research?

Keith

At 05:04 PM 5/16/03 -0400, Michael E. Mann wrote:

Tom,

Thanks for your response, which I will maintain as confidential within the small group of the original recipients (other than Ray whom I've included in as well), given the sensitivity of some of the comments made.

Whether or not their comments are ad hominem or potentially libelous is probably immaterial here (some people who have read them think they might be--in certain places, ulterior motives are implied on the part of individually named scientists in the discussion of scientific methodologies).

However, the real issue, as you point out, is whether or not their arguments and criticisms are valid. I would argue that very few of them are--I have prepared (and have

attached) a draft of replies to some of the specifics in their two papers--this is rough, and I'm working on preparing a refined version of this for use by those who are trying to combat the disinformation that the Baliunas and co. supporters are working at spreading within the beltway, with the full support of industry, and perhaps the administration. By necessity this is brief and focus on the most salient points--a point-by-point rebuttal would take a very long time.

In the meantime, Phil and I, and Ray/Malcolm/Henry D are independently working on review pieces (ours for R.O.G., Ray et al's for Science) that will also correct in more detail some of the most egregious untruths put forward by the Baliunas/Soon pieces (what one colleague of mine aptly chooses to abbreviate as "BS").

The most fundamental criticism, of course, is that the hypothesis, methods, and assumptions are absolutely nonsensical by construction--as you already pointed out. One could demonstrate that with an example, but then again, why do so when it is self evident that defining an anomaly of either wetter or dryer (what does that leave out?) relative to the 20th century (a comparison which is itself also ill-defined by the authors, since they don't use a uniform 20th century reference period for defining their qualitative anomalies, and discuss proxy records with variable resolution and temporal sampling of the 20th century) was "warmer than the 20th century" is nonsense at the most fundamental level. It defies the most elementary logic, and thus is difficult to reply to other than noting that it is nonsense by its very nature.

Would we be compelled to provide a counterexample to disprove the authors if they had asserted that "1=2"? What they have done isn't that much different...

So its one thing to throw out a bunch of criticisms, very few of which are valid. But to then turn around and present a fundamentally ill-posed, supposed "analysis" which doesn't even attempt to provide a quantitative "alternative" to past studies, to claim to have disproven those past studies, and to supposedly support the non-sequitor conclusion that the "MWP was warmer than the 20th century" is irresponsible, deceptive, dishonest, and a violation of the very essence of the scientific approach in my view. One or two people can't fight that alone, certainly not with the "artillery" (funding and political organization) that has been lined up on the other side. In my view, it is the responsibility of our entire community to fight this intentional disinformation campaign, which represents an affront to everything we do and believe in. I'm doing everything I can to do so, but I can't do it alone--and if I'm left to, we'll lose this battle,

mike

At 02:18 PM 5/16/2003 -0600, Tom Wigley wrote:

Dear folks,

I have just read the Soon et al. paper in E&E. Here are some comments, and a request.

Mike said in an email that he thought the paper contained possibly 'legally actionable' ad hominem attacks on him and others. I do not agree that there are ad hominem attacks. There are numerous criticisms, usually justified (although not all the justifications are valid). I did not notice any intemperate language.

While many of the criticisms are invalid, and some are irrelevant, there are a number that seem to me to be quite valid. Probably, most of these can be rebutted, and perhaps some of these are already covered in the literature. In my view, however, there a small number of points that are valid criticisms.

[Off the record, the most telling criticisms apply to Tom Crowley's work -- which I do not hold in very high regard.]

The real issue that the press (to a limited extent) and the politicians (to a greater extent) have taken up is the conclusions of the paper's original research.

First, Soon et al. come down clearly in favor of the existence of a MWE and a LIA. I think many of us would agree that there was a global-scale cool period that can be identified with a LIA. The MWE is more equivocal. There are real problems in identifying both of these 'events' with certainty due to (1) data coverage, (2) uncertainty in transfer functions, and (3) the noise of internally generated variability on the century time scale. [My paper on the latter point is continually ignored by the paleo

community, but it is still valid.]

So, we would probably say: there was a LIA; but the case for *or against* a MWE is not proven. There is no strong disagreement with Soon et al. here.

The main disagreements are with the methods used by Soon et al. to draw their LIA/MWE conclusion, and their conclusion re the anomalousness/uniqueness of the 20th century (a conclusion that is based on the same methods).

So what is their method? I need to read the paper again carefully to check on this, but it seems that they say the MWE [LIA] was warm [cold] if at a particular site there is a 50+ year period that was warm, wet, dry [cold, dry, wet] somewhere in the interval 800-1300 [1300-1900], where warm/cold, wet, dry are defined relative to the 20th century.

The problems with this are

- (1) Natural internally generated variability alone virtually guarantees that these criteria will be met at every site.
- (2) As Nev Nicholls pointed out, almost any period would be identified as a MWE or LIA by these criteria -- and, as a corollary, their MWE period could equally well have been identified as a LIA (or vice versa)
- (3) If the identified warm blips in their MWE were are different times for different locations (as they are) then there would be no global-mean signal.
- (4) The reason for including precip 'data' at all (let alone both wet and dry periods in both the MWE and LIA) is never stated -- and cannot be justified. [I suspect that if they found a wet period in the MWE, for example, they would search for a dry period in the LIA -- allowing both in both the MWE and LIA seems too stupid to be true.]
- (5) For the uniqueness of the 20th century, item (1) also applies.

So, their methods are silly. They seem also to have ignored the fact that what we are searching is a signal in global-mean temperature.

The issue now is what to do about this. I do not think it is enough to bury criticisms of this work in other papers. The people who have noticed the Soon et al paper, or have had it pointed out to them, will never see or become aware of such rebuttals/responses. Furthermore, I do not think that a direct response will give the work credibility. It is already 'credible' since it is in the peer reviewed literature (and E&E, by the way, is peer reviewed). A response that says this paper is a load of crap for the following reasons is *not* going to give the original work credibility -- just the opposite.

How then does one comprehensively and concisely demolish this work? There are two issues here. The first is the point by point response to their criticisms of the literature. To do this would be tedious, but straightforward. There will be at least some residual criticisms that must be accepted as valid, and this must be admitted. Cross-referencing to other review papers would be legitimate here.

The second is to demolish the method. I have done this qualitatively (following Nev mainly) above, but this is not enough. What is needed is a counter example that uses the method of *reductio ad absurdum*. This would be clear and would be appropriate since it avoids us having to point out in words that their methods are absurd. I have some ideas how to do this, but I will let you think about it more before going further.

You will see from this email that I am urging you to produce a response. I am happy to join you in this, and perhaps a few others could add their weight too. I am copying this to Jerry since he has to give some congressional testimony next week and questions about the Soon et al work are definitely going to be raised. I am also copying this to Caspar, since the last millenium runs that he is doing with paleo-CSM are relevant.

Best wishes,
Tom.

Simon,

Some comments to your questions below

At 13:46 20/05/2003 +0100, Simon J Shackley wrote:

dear Melvin, Tim, Mike, Tim, Sam and Kevin

For our analysis of acceptable leakage rates of carbon dioxide from geological storage sites, we can use the data provided in Lenton & Cannell CC paper I think. In particular, we could use your finding that to limit warming to under 0.2oC per decade, rate of increase of fossil fuel emissions has to be limited to under 0.03 GtC/yr/yr.

This would seem sufficient to avoid the peak warming which occurs in about 2250 under the IS92a emissions scenario (figure 1(c)). Is the 0.2oc / decade threshold widely accepted in the science community however?

This threshold (0.2/decade; 2degC absolute by 2100) is the most commonly cited in science-policy circles. The EU have formally adopted it as a preferred target. It's origin however is less than obvious and it's adequacy difficult to establish. And of course it also depends whether this is carried out to 2200 - the impacts of 4degC by 2200 is not the equivalent of impacts of 2degC by 2100.

My personal view is that there is much circular argument here. The first GCM experiments in the 1980s were 2xCO2 equilibrium, i.e., 550ppmv (cf. 275ppmv pre-industrial). Thus much early work used these scenarios. 550ppmv is also a commonly cited target for no other reason than this. A 60% reduction in CO2 is broadly commensurate with 550ppm stabilisation (admittedly, the range is wide coz of C cycle uncertainty; but 60% is mid-range). And (again mid-range) 550ppm leads to about a 2degC global warming, which by 2100 is 0.2degC/decade. Independent arguments for 0.2deg/decade exist for sure - e.g. rate of ecosystem migration - but as we all know (and have pointed out in our paper on external and internal definitions of dangerous climate change), no single metric is adequate.

My feeling is that the 2degC (0.2deg/decade) mantra is as much related to the early mind-set of 2xCO2 GCM experiments as it is rooted in any more substantive reasoning. One might also point out of course that the world has been warming at about 0.15degC/decade now for three decades (since the 1970s) - has this been acceptable/dangerous?

Should we also be looking at a 0.1oC / decade threshold as well?

I would regard this threshold as a very conservative (or radical - depending on how you look at it) one

Since we are only looking at the UK we will need to translate the 0.03 GtC figure into allowable rate of increase (presumably decrease) of European emissions and then pro-rata to the UK. IPCC SRES Emissions scenarios would provide some basis for doing these calculations and i'll have a look at the data they provide. Alternatively / in addition, we could use the Contraction and Convergence model of the GCI to calculate 'acceptable' rates of change (decreasing) of UK emissions into the next millenium. In Lenton & Cannell, the authors argue that: 'Early consideration should be given to leaving a fraction of fossil carbon unused, and/or to carbon capture and storage'. One implication of the work on leakage from geological storage sites is that the suggestion to use CCS to lessen eventual warming might not hold on longer timescales, depending on the rate of leakage. So does any one have any idea on what fraction of fossil carbon should be left in the ground so as to provide a cap on the eventual warming on long time scales (3000 years say)? Is there an 'accepted' threshold for eventual warming which is 'safe' and to which society can adapt? If so, what does this threshold tell us about how much carbon has to be left in the ground? A simpler way forward for us might again be to use Contraction & Convergence to provide us with an acceptable absolute level of emissions from the UK on long millenial timescales and to work backwards from that figure to calculate acceptable leakage rates for the UK.

Thanks for any help you can provide

Simon

To: "Pritchard, Norah" <norah.pritchard@metoffice.com>
Subject: Re: IPCC WG2 AR4 draft outlines - WGII outline & Chapters 2 and 13
Date: Mon Jun 2 13:49:07 2003

Dear Osvaldo and Martin,

It is very difficult to make considered input into this process at such short notice. I received the emails Wednesday afternoon, just before being away from the office for 48 hours. I also am not fully aware of the process into which this is fitting and it is the first time I have seen the WGII outline. I do however make some comments on the following:

The WGII outline

Chapter 2 on data etc.

Chapter 13 on critical damage etc.

WGII outline

Key Questions: there is, in analytical terms, very little difference between the 2nd and 4th key question you pose. The impacts under unmitigated CC (Q2) are not in any fundamental way different from the impacts under mitigated CC (Q4). 2degC warming, for example, will give broadly the same impacts whether this occurs because of strong CC policy intervention or whether it occurs because of low carbon development paths. What matters more for impacts is the rate of CC and what matters more for how important those impacts are is the development path pursued. I think this distinction between mitigated and unmitigated CC is tenuous and unhelpful. This has a bearing on the later discussions about stabilisation (where "stabilisation" is usually assumed to be, indeed often synonymous with, the result of mitigative action; actually (quasi-) stabilisation, at different levels, can occur in a world with relatively little direct CC mitigation policy).

The progression through the sections follows a rather linear and reductionist model - observed impacts, future impacts, adaptation, regions. I would have liked to have seen an early opening chapter on the nature of the dynamic relationship between climate and society (before we even start talking about climate change), this being able to bring out notions of vulnerability and adaptation - both fundamental to put on the table before we start thinking about future climate change and how important it is. This could also point out that "critical" damage is already being caused by climate and climate variability.

Under your structure, the observed impacts section (II) should surely parallel the later future impacts section (III) in terms of sectors/themes. There are only 4 themes in section II, yet 6 (different) themes in section III. Why for example is nothing said about observed impacts on urban infrastructure or on coasts? The asymmetry between these section sub-themes is itself perhaps revealing.

It seems odd that adaptation is to be addressed in all the thematic chapters in Section III *as well as* in a separate later chapter on adaptation. This situation is ripe for overlap and redundancy. Our understanding of adaptation in any case should be brought in right at the beginning (see above).

The avoiding critical damage chapter suffers from the same problem identified above - what matters is whether and how such exceedance rates can be identified, not whether they result from either a mitigated or an unmitigated scenario - this academic distinction cannot be sustained in the real world.

The regional section is in danger of repeating the mistake in the TAR, again leading to dispersion of effort and redundancy. My suggestion would be *not* to assess all new regional knowledge (again; very turgid), but instead to produce a much more streamlined section focusing on a few regional/local case studies that illustrate sharply many of the (integrating) themes introduced earlier - vulnerability, adaptation, criticality, impacts. Deliberately seek to be selective and not comprehensive.

I also do not see how the WGII chapters will be co-ordinated with the 5 cross-cutting papers identified here - again, there seems much scope for duplicitous effort and redundancy or even contradiction. And since the cross-cutting papers are really the interesting and useful ones, this suggests to me that the old traditional WG structure of IPCC is now deeply flawed (as I have said more than once before in public).

Chapter 2 - Assumptions, etc.

First question to raise is what is WGI doing in this regard? I cannot comment sensibly without knowing how WGI will tackle questions of scenarios and future projections. In section 2.3, 4th bullet: how relevant really are these "Stabilisation scenarios (mitigation)"? At the very least IPCC must clear up this issue about whether stabilisation is a short-hand for mitigation (as implied here). This is potentially misleading, since stabilisation can occur in many different worlds, by no means all of them worlds with strong CC mitigation policies. Continuation of this thinking means reality is being forced to accommodate the arbitrary thinking of the UNFCCC rather than UNFCCC being forced to take account of reality.

Also in this bullet is "Impacts of extreme climate events". Why are impacts being looked at here? Surely this is totally misplaced. What is important are scenarios - of whatever origin and methodology - that embed within them changes in the character of "extreme" weather and how we describe such changes. We should not separate this out as a separate issue surely.

Section 2.4 (the second appearance) confuses me. Much of this material appears earlier in 2.3, thus characterisations of future conditions is what 2.3 is about and also the projected changes in key drivers is what the scenarios part of 2.3 is all about. Do you mean to differentiate between methodology (2.3) and outcomes (2.4b)? And as always you will run into the problem of summarising what scenarios actually *are* assumed in this report - is there to be an IPCC 4AR standard scenario(s) that all should use? I suspect not. Resolving this problem gets to the heart of the structural problem with IPCC.

Different people will use different assumptions.

Chapter 13 - Critical Damage ...

This outline was almost unintelligible to me! For example having read the opening aims and scope statement several times, I am still not clear about the approach this chapter is

taking. Sections 13.2 and 13.3 are also extremely unclear as is section 13.4.

I think someone needs to do some clearer thinking about this chapter before sending it out for people to comment on. I have my own views on this, but at such short notice and without knowing the agreed IPCC process I'm not going to write the chapter outline for you.

Inter alia, the chapter should address the following:

- different paradigms for defining "critical"; will vary by sector, culture, etc.
- distinction between external (pronounced) definitions of critical and internal (experienced/perceived) definitions
- relationship between adaptive capacity and "critical" rates of change
- dependence of critical thresholds on sector and spatial scale
- reversibility (or not) of critical damage

... and if the use of "critical" is a euphemism for "dangerous" then it is not very subtle

- people will see through this. What is the difference between critical and dangerous?

Dear Mike

We are now developing chapter outlines for the Fourth Assessment Report of the IPCC and we write to ask if you will help us in this task. Enclosed is a one-page outline of the proposed chapter on Assumptions, Data and Scenarios, which we would like you to adjust and expand (but not to more than one and a half pages in all, please). The overall list of proposed topics to be covered in the assessment is also attached.

We would like to make the next revision to the outline in a few days so could you please return your outline to Norah Pritchard << ipccwg2@metoffice.com >> at the WGII Technical Support Unit at the UK Met Office's Hadley Centre not later than 2nd June?

The process of designing the Fourth Assessment and selecting authors is different from previously. This time the authors will not be nominated by governments and then selected until *after* the outline has been approved by IPCC Plenary this November. The outlines are therefore being widely commented on between now and mid-September, when they will be finalised. We consider your input at this time to be most important.

We appreciate that you are busy, but urge that you give a few minutes to this crucial task.

In another message we will be writing for your suggestions regarding other experts to consult in the fields of Assumptions, Data and Scenarios.

We look forward to hearing from you

With thanks and kind regards,

Osvaldo Canziani and Martin Parry

Subject: revised NH comparison manuscript

Date: Tue, 3 Jun 2003 14:51:09 -0400

Cc: Mike Mann <mann@virginia.edu>

<x-flowed>

Attached to this e-mail is a revision of the northern hemisphere comparison manuscript. First some general comments. I tried as best as possible to incorporate everyone's suggestions. Typically this meant adding/deleting or clarifying text. There were cases where we disagreed with the suggested changes and tried to clarify in the text why.

In this next round of changes I encourage everyone to make specific suggestions in terms of wording and references (e.g. Rutherford et al. GRL 1967 instead of "see my GRL paper"). I also encourage everyone to make suggestions directly in the file in coloured text or by using Microsquish Word's "Track Changes" function (this will save me deciphering cryptic penmanship; although I confess, my writing is worse than anyone's). If you would prefer to use the editing functions in Adobe Acrobat let me know and I will send a PDF file. If you still feel strongly that I have not adequately addressed an issue please say so. I will incorporate the suggestions from this upcoming round into a manuscript to be submitted. After review, everyone will get a crack at it again.

I will not detail every change made (if anyone wants the file with the changes tracked I can send it). Here are the major changes:

- 1) removal of mixed-hybrid approach and revised discussions/figures
- 2) removal of CE scores from the verification tables
- 3) downscaling of the Esper comparison to a single figure panel and one paragraph.
- 4) revised discussion of spatial maps and revised figure (figure 8).
- 5) seasonal comparisons have been revised

Several suggestions have been made for where to submit. These are listed on page 1 of the manuscript. Please indicate your preference ASAP and I will tally the votes.

I would like to submit by late July, so if you could please get me comments by say July 15 that would be great. I will send out a reminder in early July. If I don't hear from you by July 15 I will assume that you are comfortable with the manuscript.

Please let me know if you have difficulty with the file or would prefer a different format.

Regards,

Scott

Thanks Phil, and Thanks Tom W and Keith for your willingness to help/sign on. This certainly gives us a "quorum" pending even a few possible additional signatories I'm waiting to hear back from.

In response to the queries, I will work on a draft today w/ references and two suggested figures, and will try to send on by this evening (east coast USA). Tom W indicated that he wouldn't be able to look at a draft until Thursday anyway, so why doesn't everyone just take a day then to digest what I've provided and then get back to me with comments/changes (using word "track changes" if you like).

I'd like to tentatively propose to pass this along to Phil as the "official keeper" of the draft to finalize and submit IF it isn't in satisfactory shape by the time I have to leave (July 11--If I hadn't mentioned, I'm getting married, and then honeymoon, prior to IUGG in Sapporo--gone for about 1 month total). Phil, does that sound ok to you?

Re Figures, what I had in mind were the following two figures:

1) A plot of various of the most reliable (in terms of strength of temperature signal and reliability of millennial-scale variability) regional proxy temperature reconstructions around the Northern Hemisphere that are available over the past 1-2 thousand years to convey the important point that warm and cold periods were highly regionally variable.

Phil and Ray are probably in the best position to prepare this (?). Phil and I have recently submitted a paper using about a dozen NH records that fit this category, and many of which are available nearly 2K back--I think that trying to adopt a timeframe of 2K, rather than the usual 1K, addresses a good earlier point that Peck made w/ regard to the memo, that it would be nice to try to "contain" the putative "MWP", even if we don't yet have a hemispheric mean reconstruction available that far back [Phil and I have one in review--not sure it is kosher to show that yet though--I've put in an inquiry to Judy Jacobs at AGU about this]. If we wanted to be fancy, we could do this the way certain plots were presented in one of the past IPCC reports (was it 1990?) in which a spatial map was provided in the center (this would show the locations of the proxies), with "rays" radiating out to the top, sides, and bottom attached to rectangles showing the different timeseries. Its a bit of work, but would be a great way to convey both the spatial and temporal information at the same time.

2) A version of the now-familiar "spaghetti plot" showing the various reconstructions as well as model simulations for the NH over the past 1 (or maybe 2K). To give you an idea of what I have in mind, I'm attaching a Science piece I wrote last year that contains the same sort of plot.

However, what I'd like to do different here is:

In addition to the "multiproxy" reconstructions, I'd like to Add Keith's maximum latewood density-based series, since it is entirely independent of the multiproxy series, but conveys the same basic message. I would also like to try to extend the scope of the plot back to nearly 2K. This would be either w/ the Mann and Jones extension (in review in GRL) or, if that is deemed not kosher, the Briffa et al Eurasian tree-ring composite that extends back about 2K, and, based on Phil and my results, appears alone to give a reasonably accurate picture of the full hemispheric trend.

Thoughts, comments on any of this?

thanks all for the help,

mike

Mike,

This is definitely worth doing and I hope you have the time before the 11th, or can pass it on to one of us at that time. As you know I'm away for a couple of days but back Friday.

So count me in. I've forwarded you all the email comments I've sent to reporters/fellow scientists, so you're fully aware of my views, which are essentially the same as all of the list

and many others in paleo. EOS would get to most fellow scientists. As I said to you the other

day, it is amazing how far and wide the SB pieces have managed to percolate. When it comes

out I would hope that AGU/EOS 'publicity machine' will shout the message from rooftops everywhere. As many of us need to be available when it comes out.

There is still no firm news on what Climate Research will do, although they will likely

have two editors for potentially controversial papers, and the editors will consult when papers

get different reviews. All standard practice I'd have thought. At present the editors

get no
guidance whatsoever. It would seem that if they don't know what standard practice is
then
they shouldn't be doing the job !
Cheers
Phil

At 22:34 03/06/03 -0400, Michael E. Mann wrote:

Dear Colleagues,
Eos has invited me (and prospective co-authors) to write a 'forum' piece (see below).
This was at Ellen Mosely-Thompson's suggestion, upon my sending her a copy of the
attached memo that Michael Oppenheimer and I jointly wrote. Michael and I wrote this to
assist colleagues who had been requesting more background information to help counter
the spurious claims (with which I believe you're all now familiar) of the latest
Baliunas & Soon pieces.

The idea I have in mind would be to use what Michael and I have drafted as an initial
starting point for a slightly expanded piece, that would address the same basic issues
and, as indicated below, could include some references and figures. As indicated in
Judy Jacobs' letter below, the piece would be rewritten in such a way as to be less
explicitly (though perhaps not less implicitly) directed at the Baliunas/Soon claims,
criticisms, and attacks.

Phil, Ray, and Peck have already indicated tentative interest in being co-authors. I'm
sending this to the rest of you (Tom C, Keith, Tom W, Kevin) in the hopes of broadening
the list of co-authors. I strongly believe that a piece of this sort co-authored by 9
or so prominent members of the climate research community (with background and/or
interest in paleoclimate) will go a long way in helping to counter these attacks, which
are being used, in turn, to launch attacks against IPCC.

AGU has offered to expedite the process considerably, which is necessary because I'll be
travelling for about a month beginning June 11th. So I'm going to work hard to get
something together ASAP. I'd would therefore greatly appreciate a quick response from
each of you as to whether or not you would potentially be willing to be involved as a
co-author. If you're unable or unwilling given other current commitments, I'll
understand.

Thanks in advance for getting back to me on this,
mike

Subject: Re: position paper by Mann,
Bradley et al that is a refutation to Soon et al
X-Sender: ethomps@pop.service.ohio-state.edu
To: Judy Jacobs <JJacobs@agu.org>, "Michael E. Mann" <mann@virginia.edu>
X-Mailer: QUALCOMM Windows Eudora Version 4.3

Judy and Mike -
This sounds outstanding.
Am I right in assuming that Fred reviews and approves the Forum pieces?
If so, can you hint about expediting this. Timing is very critical here.
Judy, thanks for taking the bull by the horns and getting the ball rolling.

Best regards,
Ellen

At 07:33 PM 06/03/2003 -0400, Judy Jacobs wrote:

Dear Dr. Mann,
Thanks for the prompt reply.
Based on what you have said, it sounds to me as if Mann, Bradley, et al. will not be in
violation of AGU's prohibition on duplicate publication.
The attachment to your e-mail definitely has the look and feel of something that would
be published in Eos under the "FORUM" column header. FORUM pieces are usually comments
on articles of any description that have been published in previous issues of Eos; or
they can be articles on purely scientific or science policy-related issues around which
there is some controversy or difference of opinion; or articles on current public issues
that are of interest to the geosciences; or on issues--science or broader policy
ones--on which there is an official AGU Position Statement. In this last category, I
offer, for example, the teaching of creationism in public schools, either alongside
evolution, or to the exclusion of evolution.
AGU has an official Position Statement, "Climate Change and Greenhouse Gases," which
states, among other things, that there is a high probability that man-made gases
primarily from the burning of fossil fuels is contributing to a gradual rise in mean
global temperatures. In this context, your proto-article--in the form of the attachment
you sent me-- would seem right on target for a Forum piece. However, since the Soon et
al. article wasn't actually published in Eos, anything that you and Dr. Bradley craft
will have to minimize reference to the specific article or articles, and concentrate on
"the science" that is set forth in these papers. Presumably this problem could be

solved by simply referencing these papers.

A Forum piece can be as long as 1500 words, or approximately 6 double-spaced pages. A maximum of two figures is permitted. A maximum of 10 references is encouraged, but if the number doesn't exceed 10 too outrageously, I don't make a fuss, and neither will Ellen.

Authors are now asked to submit their manuscripts and figures electronically via AGU's Internet-based Geophysical Electronic Manuscript System (GEMS), which makes it possible for the entire submission-review process to be conducted online.

If you have never used GEMS before, you can register for a login and password, and get initial instructions, by going to

[1]<http://eos-submit.agu.org/>

If you would like to have a set of step-by-step instructions for first-time GEMS users, please ask me.

Ellen indicated that she/you would like to get something published sooner rather than later. The Eos staff can certainly expedite the editorial process for anything you and your colleagues submit.

Don't hesitate to contact me with any further questions.

Best regards,

Judy Jacobs

Michael E. Mann wrote:

Dear Judy,

Thanks very much for getting back to me on this. Ellen had mentioned this possibility, and I have been looking forward to hearing back about this.

Michael Oppenheimer and I drafted an informal memo that we passed along to colleagues who needed some more background information so that they could comment on the Soon et al papers in response to various inquiries they were receiving from the press, etc. I've attached a copy of this memo.

It has not been our intention for this memo to appear in print, and it has not been submitted anywhere for publication. On the other hand, when Ellen mentioned the possibility of publishing something *like* this in e.g. the "Eos" forum, that seemed like an excellent idea to me, and several of my colleagues that I have discussed the possibility with.

What we had in mind was to produce a revised version of the basic memo that I've attached, modifying it where necessary, and perhaps expanding it a bit, seeking broader co-authorship by about 9 or so other leading climate scientists. So far, Phil Jones of the University of East Anglia, Ray Bradley of the University of Massachusetts, and Jonathan Overpeck of the University of Arizona, have all indicated their interest in co-authoring such a piece. We suspect that a few other individuals would be interested in being co-authors as well. I didn't want to pursue this further, however, until I knew whether or not an Eos piece was a possibility.

So pending further word from you, I would indeed be interested in preparing a multi-authored "position" paper for Eos in collaboration with these co-authors, based loosely on the memo that I have attached.

I look forward to further word from you on this.

best regards,

mike mann

At 04:59 PM 6/3/2003 -0400, you wrote:

Dear Dr. Mann,

I am the managing editor for Eos, the weekly newspaper of the American Geophysical Union.

Late last week, the Eos editor for atmospheric sciences, Ellen Mosley-Thompson, asked me if Eos would publish what she called "a position paper" by you, Phillip Bradley, et al that would, in effect, be a refutation to a paper by Soon et al. that was published in a British journal, Energy & Environment a few weeks ago. This Energy & Environment article was subsequently picked up by the Discovery Channel and other print and electronic media that reach the general public.

Before I can answer this question, I need to ask if you and your colleagues intend for this position paper to be published simultaneously in outlets other than Eos. If this is the case, I'm afraid it being published in Eos is a moot point, because of AGU's no duplicate publication policy: if the material has been published elsewhere first, AGU will not publish it.

I look forward to your response.

Best regrds,

Judy Jacobs

Hi Keith,

Okay, here is a zipped archive containing Jan's ring-width measurement series. The directory names are:

random

all

slope

flat

"All" contains files with "all" series; "slope" has those series Jan reckoned had curvilinear growth trends; "flat" has those series with linear growth trends; "random" are those series that Jan chose not to use. Note that I had to pull out the Mongolia data set. I would love to give you it, but Gordon would go nuts if he found out. I don't know any way around this problem.

The file names are:

01ath Athabasca

02bor Boreal

03cam Camphill

04que Quebec

05upp Upper Wright

06got Gotland

07jae Jaemtland

08lau Lauenen (site not used in paper)

09tir Tirol

10tor Tornestrask

11man Mangazeja

13pol Polar Urals

14tay Taymir

15zha Zhaschiviersk

I can't put my hands on the derived RCS indices for these sites just now, but I can find them if you want them. This at least gives you the basic data and how it was partitioned by Jan. I did not participate in this stage of the analysis, so any questions about it should be directed to Jan.

Cheers,

Ed

Hi Big Boy

You just caught me as I was about to slope off after a brutal day - we spent all day yesterday interviewing for a job we have and then someone accepted it - and now Janice tells us we don't have the money to pay at the rate the job was advertised for! This attack sounds like the last straw- from what you say it is a waste of time my looking at it but send a copy anyway. The file you have is an old version of a reconstruction output for one Tornetrask reconstruction - if it was labelled something like 990 it is the original Nature one , but 997 (i Think//1) would make it the Climate Dynamics one . Trouble is I will have to go back and find out which . Please ring if I haven't my tomorrow to remind me - and concentrate on the review for now. I will also talk about an extended nearby data set (temp) that might allow a longer more rigorous validation . Kirsten has just done Math GCSE and Amy her driving test so I have to go and pick them up. I will look at the file and be ready with an answer by midday my time. the best and a beer til then

Keith

At 09:50 AM 6/4/03 -0400, you wrote:

Hi Keith,

Okay, today. Promise! Now something to ask from you. Actually somewhat important too. I got a paper to review (submitted to the Journal of Agricultural, Biological, and Environmental Sciences), written by a Korean guy and someone from Berkeley, that claims that the method of reconstruction that we use in dendroclimatology (reverse regression) is wrong, biased, lousy, horrible, etc. They use your Tornetrask recon as the main whipping boy. I have a file that you gave me in 1993 that comes from your 1992 paper. Below is part of that file. Is this the right one? Also, is it possible to resurrect the column headings? I would like to play with it in an effort to refute their claims. If published as is, this paper could really do some damage. It is also an ugly paper to review because it is rather mathematical, with a lot of Box-Jenkins stuff in it. It won't be easy to dismiss out of hand as the math appears to be correct theoretically, but it suffers from the classic problem of pointing out theoretical deficiencies, without showing that their improved inverse regression method is actually better in a practical sense. So they do lots of monte carlo stuff that shows the superiority of their method and the deficiencies of our way of doing things, but NEVER actually show how their method would change the Tornetrask reconstruction from what you produced. Your assistance here is greatly appreciated. Otherwise, I will let Tornetrask sink into the melting permafrost of northern Sweden (just kidding of course).

Cheers,

Ed

I am really sorry but I have to nag about that review - Confidentially I now need a hard and if required extensive case for rejecting - to support Dave Stahle's and really as soon as you can. Please
Keith

At 08:00 AM 5/28/03 -0400, you wrote:

Hi Keith,

Okay, here is a zipped archive containing Jan's ring-width measurement series. The directory names are:

random

all

slope

flat

"All" contains files with "all" series; "slope" has those series Jan reckoned had curvilinear growth trends; "flat" has those series with linear growth trends; "random" are those series that Jan chose not to use. Note that I had to pull out the Mongolia data set. I would love to give you it, but Gordon would go nuts if he found out. I don't know any way around this problem.

The file names are:

01ath Athabasca

02bor Boreal

03cam Camphill

04que Quebec

05upp Upper Wright

06got Gotland

07jae Jaemtland

08lau Lauenen (site not used in paper)

09tir Tirol

10tor Tornestrask

11man Mangazeja

13pol Polar Urals

14tay Taymir

15zha Zhaschiviersk

I can't put my hands on the derived RCS indices for these sites just now, but I can find them if you want them. This at least gives you the basic data and how it was partitioned by Jan. I did not participate in this stage of the analysis, so any questions about it should be directed to Jan.

Cheers,

Ed

Dear All,

I've attached a draft (attached word document), incorporating many of the suggestions, wording, etc. I've already recieved from various of you. Some specific comments/inquiries/requests for help indicated in yellow highlighting. Waiting to hear back from Peck and Tom C (guys: if you're out there, can you give a holler, to let me know your disposition? thanks). Otherwise everyone else has indicated they're on board.

I've been in touch w/ Judy Jacobs at AGU to clarify the ground rules. Apparently we *can* refer, where necessary, to press releases, parenthetically in the piece. I think this is important in our case because there is a subtle, but important, distinction between what the papers actual purport to show, and what the authors (and their promoters) have *claimed* they show (e.g. in the Harvard-Smithsonian press release). We need to draw out this distinction-I sent Judy my paragraph on that, and she said it looks fine--so apparently its kosher.

I've avoided any reference to unpublished work however (e.g. Mann and Jones), because this opens up a can of worms. We can nicely make use of work that Keith has already done to provide a suggestion of the longer-term (past 2K) changes, for greater context...

Re, references--we necessarily have to go well over the normal 10 or so, because part of the strength of our piece is the wealth of recent studies supporting our basic conclusions.

Judy said that's ok too--especially since our text is short (by about 100 words) relative to the official (1200 word) limit. So we should try to keep it that way..ie, we need to play a zero-sum game, as much as possible, with any suggested revisions.

Re figures, Scott Rutherford has generously offered to help prepare a draft of figure 1 which I'll send on to everyone once its available.

I've also described, in the figure caption, my concept of Figure 2--clearly it would be helpful if Phil and Ray could collaborate on the preparation of this one (guys?).

Looking forward to comments, and suggested revisions. I'll just accumulate these from everyone in whatever form you prefer to provide them (emailed comments, word file w/ track changes or highlighting of changes used, etc) and try to prepare a revised draft once I've heard back from everyone.

Thanks again to everyone for their willingness to help with this and to be involved with this,

mike

Thanks Phil, and Thanks Tom W and Keith for your willingness to help/sign on. This certainly gives us a "quorum" pending even a few possible additional signatories I'm waiting to hear back from.

In response to the queries, I will work on a draft today w/ references and two suggested figures, and will try to send on by this evening (east coast USA). Tom W indicated that he wouldn't be able look at a draft until Thursday anyway, so why doesn't everyone just take a day then to digest what I've provided and then get back to me with comments/changes (using word "track changes" if you like).

I'd like to tentatively propose to pass this along to Phil as the "official keeper" of the draft to finalize and submit IF it isn't in satisfactory shape by the time I have to leave (July 11--If I hadn't mentioned, I'm getting married, and then honeymoon, prior to IUGG in Sapporo--gone for about 1 month total). Phil, does that sound ok to you?

Re Figures, what I had in mind were the following two figures:

1) A plot of various of the most reliable (in terms of strength of temperature signal and reliability of millennial-scale variability) regional proxy temperature reconstructions around the Northern Hemisphere that are available over the past 1-2 thousand years to convey the important point that warm and cold periods where highly regionally variable. Phil and Ray are probably in the best position to prepare this (?). Phil and I have recently submitted a paper using about a dozen NH records that fit this category, and many of which are available nearly 2K back--I think that trying to adopt a timeframe of 2K, rather than the usual 1K, addresses a good earlier point that Peck made w/ regard to the memo, that it would be nice to try to "contain" the putative "MWP", even if we don't yet have a hemispheric mean reconstruction available that far back [Phil and I have one in review--not sure it is kosher to show that yet though--I've put in an inquiry to Judy Jacobs at AGU about this]. If we wanted to be fancy, we could do this the way certain plots were presented in one of the past IPCC reports (was it 1990?) in which a spatial map was provided in the center (this would show the locations of the proxies), with "rays" radiating out to the top, sides, and bottom attached to rectangles showing the different timeseries. Its a bit of work, but would be a great way to convey both the spatial and temporal information at the same time.

2) A version of the now-familiar "spaghetti plot" showing the various reconstructions as well as model simulations for the NH over the past 1 (or maybe 2K). To give you an idea of what I have in mind, I'm attaching a Science piece I wrote last year that contains the same sort of plot.

However, what I'd like to do different here is:

In addition to the "multiproxy" reconstructions, I'd like to Add Keith's maximum latewood density-based series, since it is entirely independent of the multiproxy series, but conveys the same basic message. I would also like to try to extend the scope of the plot back to nearly 2K. This would be either w/ the Mann and Jones extension (in review in GRL) or, if that is deemed not kosher, the Briffa et al Eurasian tree-ring composite that extends back about 2K, and, based on Phil and my results, appears alone to give a reasonably accurate picture of the full hemispheric trend.

Thoughts, comments on any of this?

thanks all for the help,

mike

At 09:25 AM 6/4/2003 +0100, Phil Jones wrote:

Mike,

This is definitely worth doing and I hope you have the time before the 11th, or can pass it on to one of us at that time. As you know I'm away for a couple of days but back Friday.

So count me in. I've forwarded you all the email comments I've sent to reporters/fellow scientists, so you're fully aware of my views, which are essentially the same as all of the list

and many others in paleo. EOS would get to most fellow scientists. As I said to you the other

day, it is amazing how far and wide the SB pieces have managed to percolate. When it comes

out I would hope that AGU/EOS 'publicity machine' will shout the message from rooftops everywhere. As many of us need to be available when it comes out.

There is still no firm news on what Climate Research will do, although they will likely

have two editors for potentially controversial papers, and the editors will consult when papers

get different reviews. All standard practice I'd have thought. At present the editors get no

guidance whatsoever. It would seem that if they don't know what standard practice is then

they shouldn't be doing the job !

Cheers

Phil

At 22:34 03/06/03 -0400, Michael E. Mann wrote:

Dear Colleagues,

Eos has invited me (and prospective co-authors) to write a 'forum' piece (see below).

This was at Ellen Mosely-Thompson's suggestion, upon my sending her a copy of the attached memo that Michael Oppenheimer and I jointly wrote. Michael and I wrote this to assist colleagues who had been requesting more background information to help counter the spurious claims (with which I believe you're all now familiar) of the latest Baliunas & Soon pieces.

The idea I have in mind would be to use what Michael and I have drafted as an initial starting point for a slightly expanded piece, that would address the same basic issues and, as indicated below, could include some references and figures. As indicated in Judy Jacobs' letter below, the piece would be rewritten in such a way as to be less explicitly (though perhaps not less implicitly) directed at the Baliunas/Soon claims, criticisms, and attacks.

Phil, Ray, and Peck have already indicated tentative interest in being co-authors. I'm sending this to the rest of you (Tom C, Keith, Tom W, Kevin) in the hopes of broadening the list of co-authors. I strongly believe that a piece of this sort co-authored by 9 or so prominent members of the climate research community (with background and/or interest in paleoclimate) will go a long way in helping to counter these attacks, which are being used, in turn, to launch attacks against IPCC.

AGU has offered to expedite the process considerably, which is necessary because I'll be travelling for about a month beginning June 11th. So I'm going to work hard to get something together ASAP. I'd would therefore greatly appreciate a quick response from each of you as to whether or not you would potentially be willing to be involved as a co-author. If you're unable or unwilling given other current commitments, I'll understand.

Thanks in advance for getting back to me on this,

mike

Judy and Mike -

This sounds outstanding.

Am I right in assuming that Fred reviews and approves the Forum pieces?

If so, can you hint about expediting this. Timing is very critical here.

Judy, thanks for taking the bull by the horns and getting the ball rolling.

Best regards,

Ellen

At 07:33 PM 06/03/2003 -0400, Judy Jacobs wrote:

Dear Dr. Mann,

Thanks for the prompt reply.

Based on what you have said, it sounds to me as if Mann, Bradley, et al. will not be in violation of AGU's prohibition on duplicate publication.

The attachment to your e-mail definitely has the look and feel of something that would be published in Eos under the "FORUM" column header. FORUM pieces are usually comments on articles of any description that have been published in previous issues of Eos; or they can be articles on purely scientific or science policy-related issues around which there is some controversy or difference of opinion; or articles on current public issues that are of interest to the geosciences; or on issues--science or broader policy ones--On which there is an official AGU Position Statement. In this last category, I offer, for example, the teaching of creationism in public schools, either alongside evolution, or to the exclusion of evolution.

AGU has an official Position Statement, "Climate Change and Greenhouse Gases," which states, among other things, that there is a high probability that man-made gases primarily from the burning of fossil fuels is contributing to a gradual rise in mean globab temperatures. In this context, your proto-article--in the form of the attachment you sent me-- would seem right on target for a Forum piece. However, since the Soon et al. article wasn't actually published in Eos, anything that you and Dr. Bradley craft will have to minimize reference to the specific article or articles, and concentrate on "the science" that is set forth in these papers. Presumably this problem could be solved by simply referencing these papers.

A Forum piece can be as long as 1500 words, or approximately 6 double-spaced pages. A maximum of two figures is permitted. A maximum of 10 references is encouraged, but if the number doesn't exceed 10 too outrageously, I don't make a fuss, and neither will Ellen.

Authors are now asked to submit their manuscripts and figures electronically via AGU's Internet-based Geophysical Electronic Manuscript System (GEMS), which makes it possible for the entire submission-review process to be conducted online.

If you have never used GEMS before, you can register for a login and password, and get initial instructions, by going to

[1]<http://eos-submit.agu.org/>

If you would like to have a set of step-by-step instructions for first-time GEMS users, please ask me.

Ellen indicated that she/you would like to get something published sooner rather than later. The Eos staff can certainly expedite the editorial process for anything you and your colleagues submit.

Don't hesitate to contact me with any further questions.

Best regards,

Judy Jacobs

Michael E. Mann wrote:

Dear Judy,

Thanks very much for getting back to me on this. Ellen had mentioned this possibility,

and I have been looking forward to hearing back about this.

Michael Oppenheimer and I drafted an informal memo that we passed along to colleagues who needed some more background information so that they could comment on the Soon et al papers in response to various inquiries they were receiving from the press, etc. I've attached a copy of this memo.

It has not been our intention for this memo to appear in print, and it has not been submitted anywhere for publication. On the other hand, when Ellen mentioned the possibility of publishing something *like* this in e.g. the "Eos" forum, that seemed like an excellent idea to me, and several of my colleagues that I have discussed the possibility with.

What we had in mind was to produce a revised version of the basic memo that I've attached, modifying it where necessary, and perhaps expanding it a bit, seeking broader co-authorship by about 9 or so other leading climate scientists. So far, Phil Jones of the University of East Anglia, Ray Bradley of the University of Massachusetts, and Jonathan Overpeck of the University of Arizona, have all indicated their interest in co-authoring such a piece. We suspect that a few other individuals would be interested in being co-authors as well. I didn't want to pursue this further, however, until I knew whether or not an Eos piece was a possibility.

So pending further word from you, I would indeed be interested in preparing a multi-authored "position" paper for Eos in collaboration with these co-authors, based loosely on the memo that I have attached.

I look forward to further word from you on this.

best regards,

mike mann

At 04:59 PM 6/3/2003 -0400, you wrote:

Dear Dr. Mann,
I am the managing editor for Eos, the weekly newspaper of the American Geophysical Union.
Late last week, the Eos editor for atmospheric sciences, Ellen Mosley-Thompson, asked me if Eos would publish what she called "a position paper" by you, Phillip Bradley, et al that would, in effect, be a refutation to a paper by Soon et al. that was published in a British journal, Energy & Environment a few weeks ago. This Energy & Environment article was subsequently picked up by the Discovery Channel and other print and electronic media that reach the general public.
Before I can answer this question, I need to ask if you and your colleagues intend for this position paper to be published simultaneously in outlets other than Eos. If this is the case, I'm afraid it being published in Eos is a moot point, because of AGU's no duplicate publication policy: if the material has been published elsewhere first, AGU will not publish it.
I look forward to your response.
Best regards,
Judy Jacobs

Thanks Kevin,

Those are helpful--Tom C. has returned from travels and will be providing comments shortly.

Will incorporate those and any others I receive into a revised version, which I hope to send out (w/ Figure 1 included) tonight or tomorrow,
mike

p.s. Tom W is taking the lead on preparing a companion, more targeted commentary, to be submitted to "Climate Research". Any one else interested should contact Tom...

At 05:16 PM 6/6/2003 -0600, Kevin Trenberth wrote:

Good job. I am attaching marked up copy with few suggestions.
Kevin
Michael E. Mann wrote:

Dear all,
Here is my best attempt to incorporate everyone's suggestions, views, etc. One major change you'll notice is that the final item (the one on co2 increase and recent warming) was eliminated, because it seemed to open a can of warms, and also distract from the central message. Note that, with the number of references we have, we are currently just about at the word limit for the piece. We shouldn't go over 1400 words, which puts some tight constraint on any additions, etc.
I hope to forward a draft of Figure 1 later on this afternoon. I'm assuming that Phil can take care of Figure 2 (Phil?--Scott has graciously indicated his willingness to help if necessary), but its pretty clear what this figure will show, so I don't think its that essential that we have that figure done to try to finalize the draft.
I'll attempt one final(?) revision of the text based on any remaining comments you may have--please try, if possible, to keep the suggested changes minimal at this point. I'll assume that anyone we haven't yet heard back from in the author list over the next day

or so is unable to be a co-author, and will respectfully drop them from the author list any related future emailings.

Thanks all for your help. Its rare to have every single co-author make substantial contributions to improving the draft, and that was clearly the case here...

At 10:48 10/06/03 -0400, Scott Rutherford wrote:

Phil and others,

Here is a revised figure. What do you think?

Scott

On Tuesday, June 10, 2003, at 07:21 AM, Phil Jones wrote:

Scott (and Mike if he's still there),

The three of us have been through the text, Fig 1 and decided what to put in Fig 2.

Tim is doing Fig 2 (9 long series - we'll send when we have it). I'm modifying the text

slightly - adding in refs that are missing (mostly with Fig 2) and generally tidying up.

Keith is working on the final sentence of the penultimate para. We all agree with this,

but it could be misinterpreted - so trying to avoid this.

WRT Fig 1.

There are quite a few changes we think would improve things and make it more consistent, all to the labelling.

1. Add et al to Bauer and Gerber (twice).
2. Years only in for Mann et al., so this is the only one where refs would be ambiguous.
3. So, Briffa et al 2000 becomes Briffa and Osborn 1999
4. Briffa et al, 2001 becomes Briffa et al .

5 Remove Long instrumental - the orange line from the plot and key.

It isn't explained in the caption, nor in the text.

6. As the grey line may not be seen under the grey shading, we think that all lines should

be as thin as the grey one. Some are thicker than others - can all be the same thinness.

7. Back to key, change Optimal borehole (Mann et al, 2003) to Mann et al. 2003 (Optimal

borehole) for consistency with the others.

8 . Most important is the SCALING. Needs to be clear which are scaled (to annual) and which

aren't. Text in caption is ambiguous. So can you tell us which is scaled (to annual) and

which aren't. If they are scaled then key should say - scaled 1856-1980 as with Jones et al .

Does this apply to Briffa and Osborn and to Briffa et al (the grey and orange lines).

9. Whilst on scaling are all scaled or regressed? Scaling we think of as giving the same

mean and variance. Regression does this also but which has been used.

10. Finally, Figure would look good with a thin black line along the zero line from 0 to 2000.

Call me or Tim if anything you don't follow. Try Mike as well. I sent him an email earlier

today and he'd already put his reply message up for the next 4-5 weeks.

Cheers

Hi Scott,

I concur w/ your assessment--keeping the figure the way it is now is preferable in my opinion...

mike

At 02:23 PM 6/10/2003 -0400, Scott Rutherford wrote:

Dear All,

I agree that figure 1 is very busy, but I'm not sure that is a bad thing in this case because we aren't trying to highlight differences between reconstructions/models or single out one or two from the rest. I think the current figure illustrates the range of reconstructions, the range of models and how well they agree (similar to one of our original ideas of a "cloud of reconstructions").

If we put the models into a separate panel we will need a curve common to both panels that people can use as a reference. If we go with the two panel figure I suggest that the second panel include the models, the Mann et al. 1999 reconstruction with uncertainties and the instrumental record.

I'll leave it to the group to decide.

-Scott

On Tuesday, June 10, 2003, at 01:16 PM, Michael E. Mann wrote:

I don't really like the idea of changing the figure dramatically at this point.

If we have to, I suggest the following options:

- 1) Take out one of the model simulation results--e.g. Gerber et al w/ the lower sensitivity
- 2) If we want to adopt Kevin's two panel strategy, then show the model results along w/ the gray-shaded uncertainty region from the top (reconstructions) panel. And show the instrumental record in both panels.

Anyway, up to you guys...

mike

At 10:59 AM 6/10/2003 -0600, you wrote:

Phil

Thanks for the great work.

Some reactions.

- 1) Fig. 1 is very busy and perhaps unduly crowded. My reaction is to take the model results out and put them in a separate panel. The separate panel would fit along side the key. But better below the main figure.

Can we change "gridded and arealy weighted" to "gridded, area-weighted..")

What is "optimal borehole",? Should "optimal" be in quotes?

2) Fig. 2: Can we please add a country to each name for those that don't have them?

Increased spacing between them would be nice.

Thanks

Kevin

Phil Jones wrote:

Dear All,

Keith, Tim and I have been at this for part of the day. Scott has also redrawn Fig 1.

Attached is the latest draft, which includes Kevin's from about 1 hour ago, but not Ray's

latest email.

Fig 1 from Scott is OK to us here. Fig 2 is a draft. Tim needs to space the series

out a little. To use all these we've needed to add a load of references. Getting these and

making the captions OK has taken most time and the drawing of Fig 2.

Hopefully we can all agree to this in the next day or so, then I'll submit on say

Thursday UK morning time, so you've all got all day today and tomorrow.

We've been through the text carefully and all happy with it.

Apologies - no time to make Fig 2 pdf. Hope all can see postscript. We still need to work

on the captions and tidy the refs a little more.

We'll be back at 8.30 tomorrow UK time. Peck - you've got 2 days to say yes/no !

Cheers

Hi Keith,

no problem...Responses below. let me know what you think...

thanks,

mike

At 03:01 PM 6/10/2003 +0100, Keith Briffa wrote:

thanks for that Mike - sorry but just a few more questions

the reference to "agree remarkably well with the proxy-based reconstructions (Figure 1)

" [later part of paragraph] . Unfortunately , the Bauer et al curve clearly does not -

at least from AD 1100 to 1400!

Again some qualifyer is needed - perhaps "for the most part , agree well " ?

Yes, "remarkably" is an overstatement given that, as you say, Bauer et al does stray some bit.

How about simply:

"Agree with the proxy-based reconstructions within estimated uncertainties (Figure 1)".

and later [middle of the 6th paragraph],

"relative hemispheric warmth during the 10th to 12th centuries" is ambiguous and we

prefer "relative hemispheric warmth during much of the the 10th,11th and 12th centuries"

yep, better...

but also , where we say [just below] "the specific periods of cold and warm apparent for Europe differ significantly from those for the Northern Hemisphere as a whole." , to what evidence of European anomalies are we referring?

ahh--I left that open-ended, for Phil and you guys to deal with as you see best. I was anticipating that Figure 2 would include an appropriate proxy series or two for Europe (CET, Fennoscandia?) that would make this point. But why don't you guys revise the wording, as necessary, based on Figure 2?

Hi Phil et al,

Re, Malcolm co-authorship--big oversight on my part. Can you ask Ellen if we can add his name (i.e., just say it was 'accidentally left off'), where it belongs alphabetically in the list.

I've talked to Malcolm on the phone. The PC #1 **is** the right one--but Malcolm has raised the valid point that we need to cover our behinds on what was done here, lest we be vulnerable to the snipings of the Idsos and co (i.e., that non-climatic influences on recent growth were nominally dealt w/, as in MBH99).

Malcolm is supposed to be sending some text to Phil.

So, can we incorporate his small bit of text, and add his name, and then resubmit to AGU ASAP?

Thanks all for all the help here. Now, I better get back to my newlywed wife!
mike

Mike,

Malcolm has just called Keith. He's been with Ray. Apart from probably being a little

miffed off he's not on the article, he says that the W. US series in Figure 2 is wrong.

He says
